ACKNOWLEDGEMENTS

I am indebted to many individuals who have over the course of my life provided support that has helped me get to where I am today.

I would like to thank Dr. Russell Ivy, who has patiently and diligently worked with me over the last three years. As my advisor, Dr. Ivy has gone above and beyond what an advisor is expected to do and for that I am incredibly grateful. I would also like to thank my dissertation committee: Dr. Yanmei Li, Dr. Charles Roberts, and Dr. Maria Fadiman. Dr. Li provided valuable guidance for my methodology and statistical analysis. Dr. Roberts offered a wealth of constructive detail that supported my research. Dr. Fadiman introduced me to aspects of social problems that I hadn't considered which resulted in a more comprehensive perspective on housing issues.

The inspiration for this dissertation can be attributed to Jim Carras, my former professor and now colleague and friend. Jim gave me the opportunity to work on local projects in economic development, community redevelopment, and, most importantly, low-income housing.

I would like to thank Michael Moise, who has been my primary research assistant over the course of this project. Not only does Michael's perseverance and remarkable determination serve as a role model for his peers, but also grants hope for social policy advocates. I would also like to thank Hilton Cordoba, who has provided instruction and guidance for using ArcGIS; Serge Atherwood, who proofread and edited my

Dissertation; and Alena Alberani, who has been an inspiration to me since the first day we met.

I would like to recognize my parents, family, and friends for their continued encouragement, constructive feedback, and support not only during the last three years but over the course of my life. My parents provided me an environment full of opportunities and I now truly understand and appreciate how this upbringing has played an instrumental role in my success. Last, I would like to thank my grandmother, Adelaide "Dale" H. Sposito.

ABSTRACT

Title: The Landscape of Prosperity and Poverty in Urban Qualified Census Tracts: Deconcentrating Poverty or Perpetuating Existing Conditions?
Institution: Florida Atlantic University
Dissertation Advisor: Dr. Russell Ivy
Degree: Doctor of Philosophy
Year: 2012

The federal Low Income Housing Tax Credit (LIHTC) program, authorized in 1986, has gained recognition over the last decade as America's largest place-based subsidized housing production program. The Qualified Census Tract (QCT) provision of the LIHTC program awards developers for projects built in high-poverty neighborhoods. This research examines whether the QCT provision is deconcentrating poverty or instead perpetuating it by comparing QCTs with LIHTC projects against QCTs with no LIHTC projects.

In this study, a socioeconomic index is created to examine changes in socioeconomic variables (poverty, income, unemployment, and education) using 1990 Decennial Census data and 2005-2009 American Community Survey data for the twenty most populated MSAs in the United States to determine how LIHTC projects have changed the landscape of poverty in urban QCTs. Control and target groups were

established to analyze the impact of LIHTC projects in QCTs. The control group consists of QCTs with no LIHTC projects and the target group contains QCTs with LIHTC projects. In order to determine how the socioeconomic variables have changed over the last fifteen years, the percent change from 1990 to 2005–2009 was calculated for each tract. Independent Sample T-tests were conducted at the national level, MSA level, and county level (when the sample size was large enough) using SPSS to determine if the difference in the target group's derived socioeconomic index and variables were significantly different from those of the control group. The findings indicate the target groups overwhelmingly outperformed the control groups for the socioeconomic index and every variable except unemployment. The results of this study may be valuable for policymakers to develop thresholds and guidelines for future LIHTC development in areas concentrated by poverty.

DEDICATION

This manuscript is dedicated to the apprentices of the Housing Authority of the City of Fort Lauderdale's Step-Up Apprenticeship Initiative. The apprentices continually remind me of how imperative it is that we rethink and continue to advance our low-income housing and social policies in America. Uneven geographies of opportunities continue to persist and it is nowhere more prevalent than for the economically disadvantaged in South Florida. Expanding housing choice, providing job training for low-income residents, and continuing research that improves our policies and programs are necessary to create sustainable communities that can be enjoyed by all socioeconomic groups. I hope that continued research and improved policies and programs make it possible for the apprentices' children to escape the daily hardships their parents endure and we are able to bestow a community where all citizens are able to prosper.

CHAPTER 1: INTRODUCTION

Equity is a fundamental aspect of sustainable development. Equity exists when all individuals have equal access to community resources and opportunities. Although communities are adopting sustainable principles and policies, the implementation of the equity concept is often complex and challenging. How do communities provide equal access to education, livelihood, and resources? This author suggests that one way to approach equity is by examining housing development patterns, particularly in low-income areas.

Uneven development of metropolitan America is a direct result of policy decisions. A look back at several decades of federal housing policies points to a persistently uneven distribution of resources and opportunities in distressed areas despite repeated efforts to amend such inequality. The shortage of safe, decent, affordable housing in low-poverty areas reinforces economic segregation (Bookbinder et al., 2008). Concentrating poverty has had significant negative consequences, leading to social isolation and limiting economic opportunities (Wilson, 1987). According to Logan (2003), “The housing market and discrimination sort people into different neighborhoods, which in turn shape residents’ lives – and deaths. Bluntly put, some neighborhoods are likely to kill you” (p.33).

By promoting affordable housing in neighborhoods with less poverty and more educational opportunities and employment choices, economically disadvantaged families

have a better chance at improving their lives. As part of present-day efforts to alter uneven development and deconcentrate poverty, the U.S. Department of Housing and Urban Development (HUD) promotes racially, ethnically, and socioeconomically diverse communities and provides access to neighborhoods where structural disadvantages have persisted. This has been seen in efforts since the 1970s when poverty deconcentration gained popularity (Hays, 1995) and with programs such as HOPE VI, the Gautreaux program, Moving to Opportunity (MTO) demonstration, and the emphasis placed on the jobs-housing mismatch (Williamson, Smith, & Strambi-Kramer, 2009).

Another example of a housing program with poverty deconcentration as a goal is the Low Income Housing Tax Credit (LIHTC) program. LIHTC is the primary vehicle in delivering new affordable rental housing in the United States and has produced nearly 1.5 million units over the past 20 years (Williamson, Smith, & Strambi-Kramer, 2009). Over 1.8 million LIHTC units had been placed in service by the end of 2007 (Horn & O'Regan, 2011). This is one-third more than the number of public housing units built. According to the Federal Reserve Bank of St. Louis (2009), by 2009 the LIHTC program had produced over two million housing units and financed an average of 100,000 rental units per year. Approximately one of every eight rental units built in the United States is subsidized by the LIHTC program (McClure, 2010).

A goal of the LIHTC program is to help deconcentrate impoverished renters by providing access to low-poverty neighborhoods. However, early research on the program revealed that LIHTC development continues to be placed in low-income neighborhoods (Newman & Schnare, 1997; Cummings & DiPasquale, 1999). LIHTC developments are more likely to be located in areas with a higher concentration of minorities and poverty;

one-third of all LIHTC projects are placed in inner-city neighborhoods with a large share of minorities and high-poverty (Muralidhara, 2006). The LIHTC program has been used to provide better housing in distressed areas as opposed to placing affordable housing in more affluent neighborhoods (Cummings & DiPasquale, 1999). McClure (2006) found that LIHTC units are more likely to be in high-poverty census tracts than other rental units. Further, by 2007, 40.6 percent of the LIHTC properties, or 41.7 percent of LIHTC units, were located in QCTs (Abt Associates Inc., 2008).

Qualified Census Tracts (QCTs) are defined in Section 42 of the Internal Revenue Code as areas where 50 percent or more of the households have incomes below 60 percent of the area median income (AMI), or where the poverty rate is 25 percent or higher (Hollar & Usowski, 2007). As an incentive to developers to replace substandard housing in low-income areas, QCTs were identified in the amendments to the tax code in the Omnibus Budget Reconciliation Act of 1989. Projects in QCTs qualify for 30 percent more tax credits than developments placed in non-QCT census tracts. Thus, the Qualified Census Tract provision is intended to entice developers to place low-income housing in high-poverty areas. This is a concern because additional low-income units added to a saturated market can increase poverty concentration (McClure, 2010). The QCT bonus may be a leading cause of LIHTC development being concentrated in distressed areas plagued by high-poverty (Hollar & Usowski, 2007; Oakley, 2008; O'Neill, 2008; Williamson, Smith, & Strambi-Kramer; 2009; Van Zandt & Mhatre, 2009).

Hollar and Usowski (2007) recognize that, even though the QCT provision has been used now for nearly twenty years, there exists a lack of research on the impact of the provision. In establishing the provision, Congress assumed that areas with high-poverty

and low-income households are in the greatest need for affordable rental housing. However, are there additional areas in need of low-income housing subsidies since affordability and the existing housing supply are not acknowledged in the designation process? Further, what is the impact of developing additional low-income housing in high-poverty neighborhoods?

Oakley (2008) noted, “A major contributing factor [to the concentration of poverty] is the provision of the QCT bonus, an integral policy component of the LIHTC program. Thus, a provision of the program designed to encourage private developers to provide affordable housing in the more disadvantaged neighborhoods has to some extent mitigated the secondary goal of providing more economic diversity in LIHTC neighborhoods” (p. 624). Likewise, O’Neill (2008) questioned the effectiveness of the QCT incentive.

One year later, the results of the Williamson, Smith, and Strambi-Kramer (2009) study suggested that further research is needed to determine whether the benefits of neighborhood revitalization within QCTs more than offset the social costs of further concentrating poverty in these tracts. The study examined the relationship between Housing Choice Vouchers (HCVs) and the LIHTC program in the state of Florida. The findings revealed that 30 percent of the HCVs used in tax credit projects are located in QCTs even though less than 12 percent of LIHTC projects in Florida are located in QCTs. This finding is concerning because the large share of voucher holders in QCTs may continue patterns of poverty concentration (Williamson, Smith, & Strambi-Kramer, 2009).

Placing additional low-income housing in these areas may concentrate poverty and have perpetuating effects. The IRS, not HUD, administers the LIHTC program, so it has not been subject to the same fair housing laws as other subsidized housing programs. LIHTC developers select the location of their project and are only required to comply with local residential development laws. The QCT bonus and lack of oversight has resulted in many projects being placed in high-poverty and minority-concentrated areas. This issue has been elevated in lawsuits where state allocating agencies have been accused of concentrating LIHTC developments in poor minority neighborhoods (Horn & O'Regan, 2011).

Is it reasonable to believe that the LIHTC program could be perpetuating the concentration of poverty? Horn and O'Regan (2011) examined whether the use of LIHTC developments in high-poverty and high-minority neighborhoods were associated with increased racial segregation in metropolitan areas and raised a similar point with regard to metropolitan segregation. There are several reasons why they believe it is reasonable that the LIHTC program could be associated with increased racial segregation. These same reasons may also be applicable to the concentration of poverty. First, the LIHTC program is large in scale; LIHTC units account for 10.2 percent of the U.S. metropolitan housing stock. Second, new low-income developments in a neighborhood can change the spatial patterns of households. Likewise, the composition of nearby neighborhoods may also change since households may be removed that would have otherwise remained. Last, the 30-year affordability provision may play a role in the composition of the neighborhood. The results of the study found that LIHTC projects do not contribute to increased segregation, even those in high-poverty neighborhoods. In fact, the increase in

the use of tax credits from 1980 to 2000 is associated with the decline in segregation. In addition, increased LIHTC units developed by nonprofits in QCTs in central cities are associated with a decrease in minority segregation (Horn & O'Regan, 2011).

It is evident that one of the most persistent questions in the LIHTC literature concerns the effectiveness of the 30 percent QCT bonus. Although previous research has examined the impact of LIHTC development on neighborhoods, this is the first analysis that examines the QCT provision and how neighborhoods with LIHTC development are performing socioeconomically in comparison to non-LIHTC QCTs. This research examines whether the QCT provision is deconcentrating poverty and improving socioeconomic conditions or instead perpetuating it. The key hypothesis of this study is that QCTs with LIHTC projects will outperform QCTs without LIHTC projects. The results of this study will clarify the impact of LIHTC development on distressed neighborhoods and whether LIHTC projects in QCTs exacerbate the concentration of poverty. These findings may be valuable for policymakers in formulating guidelines for future LIHTC allocation in high-poverty census tracts.

CHAPTER 2: LITERATURE REVIEW

This chapter begins by providing background information on the Low-Income Housing Tax Credit (LIHTC) program and describing the fundamentals of Qualified Census Tracts (QCTs). This introduction is followed by several studies on LIHTC that provide a better understanding of the program. First, studies that discuss the location of LIHTC projects are presented, followed by a section that focuses on studies that have examined the impact of LIHTC projects on neighborhoods. Last, the chapter concludes by discussing how this study will contribute to the LIHTC program literature.

2.1 Low-Income Housing Tax Credit Program Background

During the 1980s, the Reagan administration substantially changed housing policy and the federal government's role in housing. Funding for low-income housing was severely cut, urging local housing organizations to turn to the private sector to help build unsubsidized low-income housing. HUD and the IRS initiated several policy tools, including tax policy, regulation, loans, and loan guarantees, to incentivize the for-profit sector to participate in shaping new programs and delivering services (Erickson, 2009). One such program created from this new policy direction was the Low-Income Housing Tax Credit (LIHTC).

LIHTC was created under the provisions of the Tax Reform Act of 1986. The tax credit is used to finance the construction and rehabilitation of affordable rental housing. It gives investors a dollar-for-dollar reduction in their federal tax liability and provides

equity to finance the costs of housing development so that the rental prices of units can be lower than market rate. Congress enacted the LIHTC program to decrease the cost to the federal government of providing subsidized housing while recognizing the need to continue federal housing assistance (Muralidhara, 2006). The LIHTC program offers a nine percent and four percent credit. The majority of new construction and major rehabilitation projects are eligible for the nine percent credit. The four percent credit is typically used as gap financing for projects using tax-exempt financing or other subsidies (Federal Reserve Bank of St. Louis, 2009). Typically, the nine percent credit is equal to approximately 70 percent of qualified development costs, and the four percent credit is equal to approximately 30 percent of the qualified development costs (Deng, 2004).

Single-family homes, duplexes, townhomes, and apartment buildings are all eligible housing types under the LIHTC program. A project may include multiple buildings. The program provides housing for families or special needs populations such as professional artists, the elderly, or the disabled. For all projects placed in service between 2003 to 2007, approximately 53 percent were for families, 27 percent for the elderly, 12 percent for the disabled, and 4.5 percent for the homeless (Abt Associates Inc., 2008). The majority of tax credit projects are new construction, but the tax credits may also be used for rehabilitation. Between 1995 and 1997, approximately 63 percent of LIHTC developments were new construction and 35 percent were rehabilitation. Remaining projects comprised of both new construction and rehabilitation (Abt Associates Inc., 2008).

The allocation process for LIHTC is complex. The process begins at the federal level with each state's Housing Finance Agency (HFA) receiving an annual LIHTC

allocation. At its inception, states received \$1.25 per person. The allocation has since increased to the greater of \$2.15 per person or \$2,465,000. Unallocated tax credits are added to a national pool and then redistributed to states eligible for excess allocation; i.e., states that used their entire allotment of tax credits (Keightley, 2009).

State housing agencies allocate credits to developers through a competitive application process according to their Qualified Allocation Plan (QAP), usually on a bi-annual basis. The types of developers that compete for the credits include for-profits, non-profits, joint ventures, partnerships, limited partnerships, trusts, corporations, and limited liability corporations. Between 1995 and 2007, the non-profit sector accounted for approximately 27.5 percent of all LIHTC development (Abt Associates Inc., 2008). Developers apply for tax credits by submitting proposals to the state HFA. The scoring criteria of applications are different in each state but priority is usually given to projects with the longest period of affordability; projects are required to remain affordable and serve low-income households for 30 years, but some applicants propose affordability periods that extend longer than 30 years. Additional criteria include QCTs that are a part of a community revitalization plan, are urban infill developments, and serve the lowest income households. In most states, points are assigned to various elements in the application and projects with the most points are selected until the money runs out. These elements include, but are not limited to: location; local housing demand; proximity to opportunities such as jobs, transportation, and grocery stores; resident characteristics; building characteristics; and cost (Baum-Snow & Marion, 2008). Most states usually receive two to four more tax credit applications than their federal allotment. The State Housing Finance Agencies Factbook indicates Hawaii was the only state that received

more tax credits than applied for in 2005 (Baum-Snow & Marion, 2008). On average, one project out of five may receive an allocation of tax credits (Keightley, 2009).

Developers offer tax credits to investors in exchange for equity to fund the construction costs of the project. The equity provided by investors does not finance all the development costs. Developers will also use conventional mortgages, construction loans, grants, state tax credits, or other financial resources to fund the project. Developers and investors typically structure limited partnerships administered by syndicators. The developer, as the general partner, often only has a small ownership percentage but maintains the ability to construct and manage the project, whereas the investor, as the limited partner, has the majority of the ownership but plays a passive role (Keightley, 2009).

The rent that is assessed on tenants and the income of eligible tenants is restricted under the Low-Income Housing Tax Credit program. The project owner has a choice of selecting either the 20-50 or 40-60 income level tests. The 20-50 test requires that at least 20 percent of the units must be occupied by residents with incomes of 50 percent or less of the area's median gross income, adjusted for family size. The 40-60 test requires that 40 percent of the units must be occupied by residents with an income of 60 percent or less of the area's median gross income, adjusted for family size. In addition to the income test, the project owner must also comply with the gross rents test. Under the gross rents test, rents may not exceed 30 percent of the 50 percent or 60 percent (depending on the income test elected for the project) of the area's median gross income (Keightley, 2009). More than 95 percent of all existing LIHTC units have qualified as low-income (Baum-Snow & Marion, 2008).

Although rent and income are restricted, very low-income families (those under 30 percent of AMI) cannot benefit from the LIHTC program without additional subsidies since the LIHTC rents are affordable only to those with incomes between 30 and 60 percent of the area median income. Nearly one-half of all LIHTC projects have at least one resident with a Housing Choice Voucher (Climaco, Finkel, Nolden, & Vanddwalker, 2006).

2.2 Qualified Census Tracts

As an incentive to developers to replace substandard housing in low-income areas, Qualified Census Tracts were identified in the amendments to the tax code in the Omnibus Budget Reconciliation Act of 1989. Congress enacted this legislation to increase the tax credit by 30 percent for LIHTC developments built in Qualified Census Tracts or Difficult Development Areas (Hollar & Usowski, 2007; Baum-Snow & Marion, 2008). Difficult Development Areas are areas with high construction, land, and utility costs relative to the area median income (Hollar & Usowski, 2007).

QCTs were originally defined in Section 42 of the Internal Revenue Code as areas where 50 percent or more of the households have incomes below 60 percent of the area median income. This definition was modified in 2000 when Congress enacted the Community Renewal Tax Relief Act. The QCT provision was expanded to include areas where 50 percent or more of households have incomes below 60 percent of the AMI, or where the poverty rate is 25 percent or higher. The new definition, which was made effective January 1, 2002, escalated the number of designated QCTs from approximately 7,700 in 2001 to more than 9,900 in 2002 (Hollar & Usowski, 2007). However, the number of designated QCTs in a metropolitan area or non-metropolitan county cannot

exceed 20 percent of the area's population so it is likely that there are more census tracts that match the QCT definition than are presently identified (Dawkins, 2011). Decennial Census data is used to determine the tracts' qualified status; consequently, the number of tracts identified as qualified is only revised every ten years after each Decennial Census (Baum-Snow & Marion, 2008).

Recognizing the problems of concentrated poverty, some states have prohibited developers from building LIHTC projects in designated census tracts or have restricted the concentration of LIHTC projects (Bookbinder et al., 2008). An example of prohibiting LIHTC development in QCTs can be found in North Carolina's Qualified Allocation Plan, whereby, "Projects cannot be in areas of minority and low-income concentration measured by comparing the percentage of minority and low-income households in the site's census tract with the community overall" (NC 2008 QAP, p.23). However, projects in community revitalization areas are not subject to this provision.

An example of restricting the concentration of LIHTC projects can be found in the Texas Qualified Allocation Plan, which states, "[s]Staff will only recommend, and the Board may only allocate, Housing Tax Credits....to more than one Development...in the same calendar year if the Developments are, or will be, located more than one linear mile apart as determined by the Department" (TX 2008 QAP, p.18).

States have also used the scoring component and minimum threshold requirements in their Qualified Allocation Plan to dictate site selection and discourage economic concentration (Bookbinder et al., 2008). However, questions arise: what is the degree to which the LIHTC program is expanding opportunities for low-income families? Where are these projects being located? Who is living in these developments? The

research studies presented in the next several sections attempt to answer some of these questions.

2.3 LIHTC Locational Patterns Research

Several studies have examined locational patterns of LIHTC development. Freeman (2004) analyzed the characteristics and location of LIHTC developments throughout the United States. The results of this study indicate LIHTC developments have been placed in high poverty neighborhoods, with low median incomes and home values. However, in the 1990s, LIHTC neighborhoods exhibited the largest increases in homes values and incomes and the largest declines in poverty compared to other federally funded assisted housing neighborhoods with similar socioeconomic conditions (Freeman, 2004).

McClure (2006) examined whether the LIHTC program helps deconcentrate poverty by providing access to more affluent neighborhoods. The findings indicate that 38 percent of all LIHTC units placed in service from 1987 through 2003 were located in suburbs, exceeding the percentage of Housing Choice Vouchers used in suburbs. However, residents were located in neighborhoods with greater poverty than would be expected for the aggregate of all renter households: both programs placed residents in neighborhoods with approximately 19 percent poverty, whereas the poverty rate among all renting households was 16 percent (McClure, 2006).

Khadduri, Buron, and Climaco (2006) examined the number of LIHTC units in metropolitan areas placed in low and moderate-income neighborhoods. In metropolitan areas with a population of at least 250,000, the results indicate that 78 percent of LIHTC units were located in moderate (census tracts where poor people make up between 10 and

20 percent of the population) or high-poverty areas (census tracts with poverty rates greater than 20 percent). Between 1987 and 1994, the number of LIHTC units placed in low- and moderate-income census tracts was lower than in more recent years, likely due to the use of other subsidy programs in conjunction with LIHTC to target older neighborhoods and rural areas. Khadduri, Buron, and Climaco (2006) conclude that since 22 percent of all LIHTC units examined in the study with two or more bedrooms were located in census tracts with less than 10 percent poverty, there is potential for the LIHTC program to expand opportunities for low-income families.

Oakley (2008) studied spatial patterns of LIHTC developments and how successful the program has been at locating projects in more affluent neighborhoods and avoiding geographic concentrations. Atlanta, Chicago, Los Angeles, and New York City were the metropolitan areas examined. Using a descriptive analysis, Exploratory Spatial Data Analysis, and a spatial regression technique, the results indicate that the presence of a LIHTC project increased the likelihood of the production of more LIHTC development nearby. The strongest predictors of LIHTC developments included LIHTC development built prior to 1995, nearby LIHTC developments, and the presence of QCTs. The findings indicate that the LIHTC program has been more successful than other subsidized housing programs at locating projects in more affluent neighborhoods, but not entirely successful at dispersing developments throughout metropolitan areas (Oakley, 2008).

O'Neill (2008) examined the locational patterns and variation in the distribution of LIHTC projects. In the twenty-five largest U.S. cities, the spatial statistic G_i^* was used to measure clustering at the census tract level and determine the existence of any hot spots of LIHTC units. A hot spot is where the G_i^* value for a census tract was at least

two standard deviations above the mean G_i^* value for all the census tracts in that particular city. The results of this study revealed that at least one hot spot existed for all cities, clustering of LIHTC developments, and clusters in some study areas being associated with high-poverty census tracts. Industrial, ‘Rust Belt’ cities had the most clustering of LIHTC properties compared to ‘Sun Belt’ cities, which displayed the least amount of clustering (O’Neill, 2008).

Pfeiffer (2009) examined the impact of LIHTC siting policy on neighborhood and educational opportunities in Southern California. Findings indicate the majority of LIHTC developments between 2000 and 2005 were placed in high-poverty minority neighborhoods. In addition, the LIHTC developments were placed in low-performing school districts (Pfeiffer, 2009).

Van Zandt and Mhatre (2009) examined the LIHTC program in expanding the geography of opportunity for the Dallas/Fort Worth Metroplex. Nearest-neighbor analysis (Moran’s I) was used to evaluate the spatial clustering of LIHTC units. The relationship between clustering and exposure to social and educational opportunities was assessed. The findings suggest that even though LIHTC units are being placed in suburbs, these areas are not more affluent nor are they enhancing income mixing. In addition, these units are being located in areas with higher levels of poverty and minority populations with substandard safety and educational settings or in areas analogous to regional averages. This denotes that LIHTC units are neither preserving nor overcoming inequalities. Van Zandt and Mhatre (2009) cite the QCT provision as one of the reasons that may explain why the LIHTC program is not working well as a dispersal tool.

McClure (2010) evaluated whether LIHTC developments were being placed in census tracts with a shortage of affordable housing. The findings reveal that the LIHTC program is not placing development in census tracts with the greatest affordable housing shortages. This finding is true regardless of population density in the urban core, the suburbs, or a rural area. There is also a persistent shortage of rental units for the poorest households; those who fall below 30 percent of the area median income (McClure, 2010). It is important to note that Emrath (2010) comments that the affordability measure used by McClure in his study has a number of limitations that may reduce its appropriateness in evaluating LIHTC projects, such as his measure does not take into consideration affordable units that are unavailable to the targeted population. For example, units in older communities may be considered affordable but may not be habitable without substantial rehabilitation.

Yaroni (2010) examined the location characteristics of the Housing Choice Voucher program and LIHTC program from two different theoretical lenses – the community development lens and access to opportunity lens. The results of the study indicate that LIHTC is used less often as a tool to improve access to opportunity and more often for community development purposes. Neighborhoods with high poverty are associated with more LIHTC units and LIHTC housing is placed in neighborhoods with higher than average poverty rates (Yaroni, 2010).

Dawkins (2011) examined the spatial pattern of LIHTC projects in the ten largest metropolitan areas to determine if clustering was greater than complete spatial randomness. Using Ripley's K function, LIHTC projects were assessed to determine if they were clustered more than the average housing unit. The results indicate that LIHTC

projects are more clustered than other housing units in all metropolitan areas examined in this study. LIHTC clusters are more prevalent in QCTs, Difficult Development Areas (DDAs), areas with high-poverty and lower share of non-Hispanic whites, and in densely developed inner-city neighborhoods (Dawkins, 2011).

In summary, these studies indicate LIHTC development is more likely to be found in high-poverty and minority-concentrated neighborhoods and may be a direct result of incentives for building in such areas. LIHTC development tends to be more highly clustered compared to unsubsidized rental units and the presence of LIHTC projects increases the likelihood of future LIHTC development nearby. QCTs are the most likely locations for concentrations of LIHTC units exhibiting the greatest amount of clustering. The LIHTC program appears to be used less often for improving opportunities for low-income residents and more commonly for community development purposes, as the majority of units are not located in areas that expand opportunities. However, there is potential for the LIHTC program to expand opportunities for low-income residents since the program appears to be doing a better job toward this goal than traditional subsidized housing programs.

2.4 LIHTC and Neighborhood Impact Research

Several studies have examined how neighborhoods changed after LIHTC development. One of the first studies conducted, examined the impacts of federally assisted housing programs on property values in Philadelphia. The study found a slight negative effect from the LIHTC projects (Lee, Culhane, & Wachter, 1999). The results of this study may not provide an accurate picture of LIHTC projects today because it only

examined projects built between 1987 and 1989. Also, the study limited the degree to which the results could be generalized nationally since it only studied Philadelphia.

Johnson and Bednarz (2002) studied the impact of LIHTC projects built between 1995 and 1997 in three cities (Cleveland, Portland, and Seattle). Contrary to the first study, although the findings were different across cities, this study found an overall positive impact from LIHTC projects. Within 300 meters of LIHTC projects, the property values increased in all three cities. In Cleveland, as larger projects were built, the impact weakened and became negative when the neighborhood exceeded 456 units. In the modestly valued, less vulnerable neighborhoods of Portland and Seattle there was no property value impact (except in Portland when the project exceeded a threshold of 0.2 percent of all units in the area) within 301-600 meters of LIHTC projects. However, in the lower valued, more vulnerable neighborhoods of Cleveland, there was a negative impact regardless of the scale of the project (Johnson & Bednarz, 2002). Although this study is notable for its methodology, it is limited by the small number of LIHTC projects examined; fewer than six per city.

Green, Malpezzi, and Seah (2002) examined the impact of LIHTC developments on property values by using a repeat sales technique, or what appraisers call a paired-sales technique. Data was gathered on properties that sold more than once in the Madison and Milwaukee metropolitan areas between 1991 and 2000 to analyze the differences in appreciation that could be explained by proximity to LIHTC developments. Regressions using linear, quadratic, and gravity measures of distance were performed to determine the influence of the developments on property values. Regressions using neighborhood controls (poverty rates, education levels, marriage rates, income levels, and age

distribution of the population) were also executed. In Wisconsin, there was no evidence of LIHTC developments causing property values to deteriorate. In Milwaukee County, it was found that properties distant from LIHTC developments tend to appreciate more rapidly. In Waukesha and Ozaukee, there was no evidence of impact on property values, while in Madison, properties near LIHTC developments appreciated more rapidly. The researchers believe LIHTC developments are best placed in relatively affluent communities to avoid concentrated poverty since there is no evidence that property values decline from LIHTC development (Green, Malpezzi, & Seah, 2002).

Rosenthal (2007) used census data to examine how neighborhoods with LIHTC and other subsidized housing changed over time from 1950 to 2000. Specifically, economic status was examined by measuring the average income of a neighborhood relative to that of all census tracts for each MSA. Neighborhoods were then classified into groups by economic status. Regarding LIHTC projects, this nationwide study revealed that LIHTC units built between 1986 and 1990 had a positive influence on the future economic status of neighborhoods, but had little impact outside of low-income neighborhoods. As pointed out by Deng (2011), it should be noted this study did not control for confounding factors influencing neighborhood change and was more informative of the association between LIHTC projects and neighborhood change.

Baum-Snow and Marion (2008) studied the effects of LIHTC developments on neighborhoods. Their research indicates that poorer tracts receive more LIHTC units; QCT designation increases the likelihood that a LIHTC development will be built in a certain tract. The income in the neighborhood declines, especially in gentrified areas, as a result of new LIHTC developments nearby; an additional one hundred units reduces

median income by 9.3 percent. LIHTC units have a positive impact on home values, however, with every one hundred additional LIHTC units leading to a 14.9 percent increase in the median home value, except for in gentrifying areas (Baum-Snow & Marion, 2008).

Deng (2009) conducted a study that applied cluster analysis to identify Miami neighborhoods similar to LIHTC neighborhoods and compared the changes from 1990 to 2000 in these neighborhoods. The results of the study indicate that LIHTC neighborhoods, with certain exceptions, generally experienced more positive changes than control neighborhoods. The impact was the greatest when LIHTC projects were built in high-poverty inner-city neighborhoods as part of a larger revitalization effort. LIHTC housing seemed to be less effective, or even impacted a neighborhood negatively, when built in more suburban neighborhoods (Deng, 2009).

Deng conducted another study that examined the external neighborhood effect of LIHTC projects, but this time examined LIHTC projects in Santa Clara County from 1987 to 2000. A difference-in-difference hedonic regression approach was used to determine the impacts of LIHTC projects on nearby single-family property values. The study found that almost all LIHTC projects generated positive impacts on nearby property values. Housing developments built by nonprofit organizations and the county housing authority generated the greatest positive neighborhood impact, while low-income neighborhoods benefited from LIHTC developments more than any other neighborhood type. LIHTC developments in low-income areas did not significantly increase the concentration of poverty (Deng, 2011).

In summary, these studies reveal mixed results regarding the impact of LIHTC development on neighborhoods. In high-poverty inner-city neighborhoods, LIHTC development appears to have a positive impact on property values and other socioeconomic conditions. However, in vulnerable suburban neighborhoods and gentrifying areas, LIHTC projects have been found to deteriorate existing economic conditions. This may help explain why the LIHTC program is being used more often for community development purposes rather than to expand opportunities for low-income residents in more affluent neighborhoods.

2.5 Contribution to the LIHTC Program Literature

The literature on the locational placement of LIHTC development and its impact on neighborhoods has contributed greatly to our understanding of the nation's largest affordable housing production program. This research is critical for state housing agencies to allocate resources efficiently. However, further research and a clearer understanding of the impacts of LIHTC development can benefit the administration of the program. Even though the literature points to significant clustering of LIHTC units, the impact of such clustering is unknown. Clustering LIHTC units may increase the concentration of poverty and limit opportunities as LIHTC properties replace substandard housing and vacant lots in an effort to revitalize neighborhoods. Although all these studies have made important contributions to the literature on the location and impact of LIHTC development, none has specifically examined the impact of the Qualified Census Tract (QCT) provision. This study fills that research gap and assesses the impact of LIHTC development on socioeconomic conditions in QCTs.

CHAPTER 3: METHODOLOGY

The methodology chapter provides a comprehensive overview of the approach used to address the research question of whether the QCT provision is deconcentrating poverty and improving socioeconomic conditions or instead perpetuating it. First, the study area is identified and discussion follows on the selection criteria for the Metropolitan Statistical Areas (MSAs) used in this study. The next section provides a description of how the QCTs were identified, followed by a discussion on the establishment of the control and target groups and the use of the census tract relationship files. The socioeconomic variables used in the study are identified and the data collection method is examined. Last, information on how the data was analyzed is discussed. This research examines whether the QCT provision is deconcentrating poverty or instead perpetuating it by comparing QCTs with LIHTC projects against QCTs with no LIHTC projects. The key hypothesis of this study is that QCTs with LIHTC projects (target group) will outperform QCTs without LIHTC projects (control group).

3.1 Study Area

The study area identified for this research encompasses the twenty most populated Metropolitan Statistical Areas in the United States in 2010. Since the LIHTC program is a national program and used in every state, a large study area was necessary to identify any major trends that could be identified across the United States. Another reason this study area was selected is because the concentration of poverty and related

socioeconomic variables (income, unemployment, and low educational attainment) persist as a defining characteristic of urban America. Jargowsky and Bane (1991) reported that within extremely poor neighborhoods - areas where the poverty rates exceed 40 percent - the number of poor increased from 1.9 million in 1970 to 2.4 million in 1980, an increase of almost 30 percent. Kasarda (1993) found the percentage of people living in extreme poverty in the central city in 1970 was 16.5 percent and increased to 22.5 percent in 1980. By 1990, the number increased to 28.2 percent. According to Squires and Kubrin (2005), from 1970 to 1990, the number of extremely poor census tracts increased from under 1,500 to more than 3,400 and the number of poor in those tracts grew from 4.1 million to more than 8 million. In 2008, more than 44 percent of the residents in urban areas had incomes of less than half of the poverty threshold as defined by the U.S. Department of Health and Human Services; this threshold was \$21,834 for a family of four (The Brookings Institution Metropolitan Policy Program, 2010).

To identify the twenty most populated MSAs, the Population and Housing Occupancy Status: 2010 - United States -- Metropolitan Statistical Area table was used.

| Region | MSA | Population 2010 |
|-----------|--------------------------------------|-----------------|
| West | Los Angeles-Long Beach-Santa Ana, CA | 12,828,837 |
| | San Francisco-Oakland-Fremont, CA | 4,335,391 |
| | Riverside-San Bernardino-Ontario, CA | 4,224,851 |
| | Seattle-Tacoma-Bellevue, WA | 3,439,809 |
| | San Diego-Carlsbad-San Marcos, CA | 3,095,313 |
| Southwest | Dallas-Fort Worth-Arlington, TX | 6,371,773 |
| | Houston-Sugar Land-Baytown, TX | 5,946,800 |
| | Phoenix-Mesa-Glendale, AZ | 4,192,887 |

(continued on next page)

| | | |
|-----------|----------------------------------------------------|------------|
| Midwest | Chicago-Joliet-Naperville, IL-IN-WI | 9,461,105 |
| | Detroit-Warren-Livonia, MI | 4,296,250 |
| | Minneapolis-St. Paul-Bloomington, MN-WI | 3,279,833 |
| | St. Louis, MO-IL | 2,812,896 |
| Northeast | New York-Northern New Jersey-Long Island, NY-NJ-PA | 18,897,109 |
| | Philadelphia-Camden-Wilmington, PA-NJ-DE-MD | 5,965,343 |
| | Washington-Arlington-Alexandria, DC-VA-MD-WV | 5,582,170 |
| Northeast | Boston-Cambridge-Quincy, MA-NH | 4,552,402 |
| | Baltimore-Towson, MD | 2,710,489 |
| Southeast | Miami-Fort Lauderdale-Pompano Beach, FL | 5,564,635 |
| | Atlanta-Sandy Springs-Marietta, GA | 5,268,860 |
| | Tampa-St. Petersburg-Clearwater, FL | 2,783,243 |

Table 1. Study Area by Region of the Twenty Most Populated MSAs

3.2 Identifying Qualified Census Tracts

After the MSAs were identified, all Qualified Census Tracts within each MSA were selected. Using the Qualified Census Tract Table Generator and past Qualified Census Tract spreadsheets, a database of all Qualified Census Tracts was created based on the new 2000 definition for QCTs that includes 2000-2011 IRS Section 42(D)(5)(C) Metropolitan Qualified Census Tracts. Spreadsheets created before 2000 were not used because the definition for QCTs changed that year. The new definition expands the number of tracts defined as QCTs (Hollar & Usowski, 2007).

3.3 Establishing Control and Target Groups

This study is a quasi-experimental design. Control and target groups were established to analyze the impact of LIHTC projects in QCTs. The control group consists of QCTs with no LIHTC projects and the target group contains QCTs with LIHTC projects. To determine which group to assign each QCT, the QCTs in each MSA with at least one LIHTC project placed in service between 1990 and 2007 was identified. 1990 was used as the base year because Congress enacted the LIHTC program in 1986 and few large LIHTC projects were built prior to 1990. Using 1980 Census data as the base year was not practical since the majority of LIHTC projects were not built until after 1990 and using 2000 Census data would have eliminated too many QCTs with LIHTC projects.

The HUD USER GIS Service LIHTC QCT Locator was used to identify which Qualified Census Tracts contained LIHTC projects. If the locator indicated at least one LIHTC project in the QCT, the project was placed in the target group. The QCTs that contained no LIHTC projects were placed in the control group. The LIHTC Database Access was used to collect the following data on each LIHTC project: name of the project, number of units, number of low-income units, and the year the project was placed in service. Any QCT that contained at least one LIHTC development placed in service before 1990 was eliminated from the study because 1990 was established as the base year.

3.4 Census Tract Relationship Files

Once each QCT was assigned to a control or target group, U.S. Census Bureau Census Tract Relationship Files were used to determine how closely the 2000 Census tract boundaries matched 1990 Census tract boundaries. This was undertaken to make

certain that the changes in the socioeconomic variables were being analyzed for the same geographic boundaries. The Census Tract Relationship Files contain one record for each 1990 Census tract and 2000 Census tract spatial set. During this analysis, some QCTs in both the control and target groups were eliminated for the following reasons: (1) the census tract had merged or split or its boundaries were revised in a manner that encompassed an area spanning the boundaries of both a 1990 control and target group; (2) when the census tract had merged, split, or was revised and contained an area that was within the geographic boundaries of more than one control and target group; and (3) when a change had occurred and included census tracts that were not originally identified as QCTs and part of the research study.

3.5 Socioeconomic Variables and Data Collection

Data was collected from the 1990 Decennial Census Summary Tape File 3 and the 2005–2009 American Community Survey 5-Year Estimates for four socioeconomic variables (poverty, income, unemployment, and education) as shown in Table 2.

| Variable | Description | |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Poverty <i>Percent of People Below the Poverty Line</i> | Number of people in the census tract living below the poverty level divided by the census tract's total population | |
| | 1990 Decennial Census Dataset P001 and P117 | 2005 – 2009 ACS Dataset All people whose income is below the poverty level |
| Education <i>Percent of Population 25 Years of Age and Older with No High School Diploma</i> | The total number of people 25 years of age and older with no high school diploma or equivalent divided by the number of people 25 years of age and older living in the census tract | |
| | 1990 Decennial Census Dataset P013 and P057 | 2005 – 2009 ACS Dataset Less than 9th grade added to 9 th to 12 th grade, no diploma |

(continued on next page)

| Variable | Description | |
|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Unemployment <i>Unemployment Rate</i> | The total number of people 16 years of age and older unemployed divided by the total number of people 16 years of age and older in the labor force within the census tract | |
| | 1990 Decennial Census Dataset P070 | 2005 – 2009 ACS Dataset Percent Unemployed |
| Income <i>Median Household Income of the Census Tract as a Percent of the County Median Household Income</i> | The median household income of the county divided by the median household income of the census tract | |
| | 1990 Decennial Census Dataset P080A | 2005 – 2009 ACS Dataset Median household income (dollars) for total households |

Table 2. Socioeconomic Variables Used in the Study

The data used to calculate the poverty rate from the 1990 Decennial Census was P117 - Poverty Status in 1989 By Age and P001 - Persons. The total number of persons for whom their income in 1989 was below the poverty level was summed and divided by the total number of persons in the census tract to calculate a poverty rate for 1990. The 2005–2009 American Community Survey 5-Year Estimates includes a variable called ‘All People Whose Income is Below the Poverty Level’ and no calculation was necessary to obtain the poverty rate for the 2005–2009 period.

The data used to calculate educational attainment from the 1990 Decennial Census was P057 – Educational Attainment and P013 – Age. The ‘Less than 9th Grade’ row was summed with the ‘9th to 12th Grade, No Diploma’ row to obtain the total number of persons with no high school diploma. This number was divided by the total number of people 25 years of age and older, which was calculated by using data from P013. This calculation provided a percent for the total number of people 25 years of age and older in the census tract that have no high school diploma. The 2005–2009 American Community Survey 5-Year Estimates include a variable called ‘Percent High School Graduate or

'Higher' for the total population of the census tract 25 years and over. This percent was subtracted from 100 in order to obtain the education variable used for 2005–2009.

Educational attainment was selected as a socioeconomic variable to examine in this study since it is highly correlated with concentrated poverty. Coleman (1966) concluded that schools with high concentration of low-income students decrease academic achievement. In the first major study on the impact of poverty on academic achievement, it was found that achievement scores decline as the proportion of poor students in a school increases (Kennedy, 1986). Entwistle (1992) reports that the most important source of variation in educational achievement is differences in family economic status. Caldas (1997) found that poverty level, racial composition, and family composition are all strong indicators of academic performance and achievement. Lippman (1996) concluded that students in public schools with low-poverty concentration have more desirable school experiences than those in high-poverty schools on almost every measure.

The data used to calculate the unemployment rate from the 1990 Decennial Census was P070 – Sex By Employment Status. The number of employed and unemployed males and females was summed to obtain the number of people in the census tract that are in the labor force. The number of unemployed males and females was then added and divided by the total labor force to obtain the unemployment rate for 1990. The 2005–2009 American Community Survey 5-Year Estimates includes a variable for the unemployment rate, 'Percent Unemployed', and no calculation was necessary to obtain the unemployment variable for 2005–2009.

The data used to calculate the median household income of the census tract as a percent of the county median household income from the 1990 Decennial Census was P080A - Median Household Income in 1989. The county median household income was divided by the median household income for each census tract. The reason the calculation was done this way was to keep all the variables moving in the same direction. For instance, as poverty, unemployment, and educational attainment all increase, each variable worsens in performance (i.e., higher rates for poverty, unemployment, and failure to achieve a high school diploma). The 2005–2009 American Community Survey 5-Year Estimates include a variable for total household ‘Median Household Income (Dollars)’. The county median household income was divided by the median household income for each census tract for the income variable for 2005–2009.

Other variables identified in the literature are highly correlated with poverty, such as crime rates (Bjerk, 2010) or the state of physical and mental health (Haney, 2007). These variables were not used in this study because they are either unavailable in both the Decennial Census and American Community Survey datasets or cannot be found from consistent data sources for all twenty MSAs used in the study. Also, since these variables are highly correlated with poverty, it is not necessary to use them all.

The reason the 2005–2009 American Community Survey 5-Year Estimates dataset was used instead of 2010 Decennial Census data is because the variables used in this study were not collected as part of the 2010 Decennial Census. According to the U.S. Census Bureau, the American Community Survey replaced the Decennial Census long form in 2010. Even though the 2005–2009 American Community Survey 5-Year Estimates dataset is the best replacement for the 2010 Decennial Census long form, there

are several precautions that must be taken into consideration when comparing Decennial Census data with American Community Survey data. The U.S. Census Bureau states that education attainment can be compared directly, but that poverty, income, and employment can be compared only with caution. The reason for this is that ACS data is collected throughout the year on an ongoing basis and asks for a respondent's income over the past 12 months; the 1990 Census collected the income data for a fixed period of time during the last calendar year (1989). Regarding employment, responses are collected year-round for ACS data and there is a revolving reference period; however, for the 1990 Census, the reference period was the week prior to Census Day (April 1, 1990).

The U.S. Census Bureau publishes the margins of error (MOE) or ranges for all ACS estimates at the 90% confidence level. The MOE measures the uncertainty of the estimates, which can be essential when examining trends over time. Unfortunately, there is no easy way to calculate the MOE or range for the 1990 Census data. Since the calculation for the margin of error is complex for the 1990 Census data, and given the large dataset, it was not done in this study.

3.6 Data Analysis

In order to determine how the socioeconomic variables changed over the last twenty years, the percent change from 1990 to 2005–2009 was calculated for each QCT. To obtain a clear understanding of how each QCT performed, a socioeconomic index was created from four variables (poverty, income, education and unemployment) by calculating the geometric mean of the percent change in the variables. Since the geometric mean contains only positive numbers, the formula is adjusted to account for negative percent changes. In the socioeconomic index, a '1' represents no change in the

data from 1990 to 2005–2009, a number larger than ‘1’ indicates a percent increase, meaning that conditions worsened, and a number less than ‘1’ represents a percent decrease, meaning that socioeconomic conditions improved.

The mean and Independent Sample T-tests were analyzed at the national level, MSA level, and county level (when the sample size was large enough) using SPSS to determine if the difference in the target group’s socioeconomic index is significantly different from that of the control group. Independent Sample T-tests were also performed for each of the four variables (poverty, income, unemployment, and education) at the national, MSA, and county level. The results of the Independent Sample T-tests and the overall performance of each variable in the QCTs are discussed in Chapter 4.

CHAPTER 4. RESULTS

The results for each MSA are reported by region: West, Southwest, Midwest, Northeast, and Southeast (Figure 1). The QCTs for all MSAs are also examined at the national level. The summary of findings for each MSA is included within this section and the results of the Independent Sample T-tests are attached as Appendix A. The number ‘1’ in the first box in the output file called ‘Group Statistics’ for each T-test in Appendix A represents the control group (QCTs without LIHTC projects) and the number ‘2’ represents the target group (QCTs with LIHTC projects).

□

Figure 1. Study Area Regions and MSAs

In Appendix B, a summary chart is provided for each region. All attributes (i.e., significance, performance, and improvement) are broken down according to MSA and MSAs are grouped according to region. The summary charts include a synopsis of the results for each of the counties that had a large enough sample size to be examined independently. There were a total of 1,733 control QCTs and 1,022 target QCTs that were examined in this study.

4.1 Western Region

Five MSAs in the Western Region of the United States were examined for this study: Los Angeles-Long Beach-Santa Ana, CA (Los Angeles MSA), San Francisco-Oakland-Fremont, CA (San Francisco MSA), Riverside-San Bernardino-Ontario, CA (Riverside MSA), Seattle-Tacoma-Bellevue, WA (Seattle MSA), and San Diego-Carlsbad-San Marcos, CA (San Diego MSA).

Two counties in the Los Angeles MSA – Los Angeles County and Orange County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the significance of the difference between the means for the control and target groups is statistically different for the socioeconomic index, income, and education in Los Angeles County and the Los Angeles MSA (Table 3).

| Independent Sample T-tests | Socioeconomic Index | Poverty Rate | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Los Angeles County | Significant | Not Significant | Significant | Not Significant | Significant |
| Orange County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Los Angeles MSA | Significant | Not Significant | Significant | Not Significant | Significant |

Table 3. Los Angeles Independent Sample T-test Results

In Los Angeles County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9346$, $SD = 0.3083$) was outperformed by the target group ($M = 0.4982$, $SD = 0.1300$); $t(162.791) = 13.129$, $p = 0.000$. There is a significant difference in the performance of the income variable; the control group ($M = 0.0654$, $SD = 0.5150$) was outperformed by the target group ($M = -0.8840$, $SD = 0.0384$); $t(113.095) = 19.420$, $p = 0.000$. There is also a significant difference in the performance of the education variable; the control group ($M = -0.1497$, $SD = 0.4047$) was outperformed by the target group ($M = -0.3122$, $SD = 0.3925$); $t(176) = 2.618$, $p = 0.010$.

In the Los Angeles MSA, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.8761$, $SD = 0.3190$) was outperformed by the target group ($M = 0.5035$, $SD = 0.1319$); $t(190.795) = 11.800$, $p = 0.000$. There is a significant difference in the performance of the income variable; the control group ($M = -0.0822$, $SD = 0.5897$) was outperformed by the target group ($M = -0.8879$, $SD = 0.0372$); $t(132.783) = 15.643$, $p = 0.000$. There is also a significant difference in the performance of the education variable; the control group ($M = -0.1208$, $SD = 0.4317$) was outperformed by the target group ($M = -0.2800$, $SD = 0.3743$); $t(207) = 2.697$, $p = 0.008$.

Even though the difference between the control and target groups is only statistically significant for the socioeconomic index, income, and education variable, the target group outperformed the control group for every variable except unemployment (Table 4).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|--------------------|---------------------|---------|--------|--------------|-----------|
| Los Angeles County | Target | Target | Target | Control | Target |
| Orange County | Target | Target | Target | Control | Target |
| Los Angeles MSA | Target | Target | Target | Control | Target |

Table 4. Los Angeles MSA Overall Performance

The socioeconomic index improved in the target and control groups for both counties and the MSA. Poverty and unemployment did not improve from 1990 to 2005–2009 in either County or in the Los Angeles MSA. The only group in which income did not improve was the control group for Los Angeles County and the only group in which education did not improve was the control group for Orange County (Table 5).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|--------------------|---------------------|---------|--------|--------------|-----------|
| Los Angeles County | Both | Neither | Target | Neither | Both |
| Orange County | Both | Neither | Both | Neither | Target |
| Los Angeles MSA | Both | Neither | Both | Neither | Both |

Table 5. Los Angeles MSA Improvement

Two counties in the San Francisco MSA – Alameda County and San Francisco County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the significance of the difference between the means for the control and target groups is statistically different for the socioeconomic index in San Francisco County and the San Francisco MSA, for poverty in the San Francisco MSA, and for education in San Francisco County (Table 6).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Alameda County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| San Francisco County | Significant | Not Significant | Not Significant | Not Significant | Significant |
| San Francisco MSA | Significant | Significant | Not Significant | Not Significant | Not Significant |

Table 5. San Francisco MSA Independent Sample T-tests Results

In San Francisco County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 1.0455$, $SD = 0.2956$) was outperformed by the target group ($M = 0.6528$, $SD = 0.1923$); $t(20) = 3.356$, $p = 0.003$. There is also a significant difference in the performance of the education variable; the control group ($M = -0.2325$, $SD = 0.2442$) was outperformed by the target group ($M = -0.4692$, $SD = 0.2042$); $t(20) = 2.312$, $p = 0.032$.

In the San Francisco MSA, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 1.0327$, $SD = 0.2867$) was outperformed by the target group ($M = 0.8076$, $SD = 0.2717$); $t(55) = 2.880$, $p = 0.006$. There is also a significant difference in the performance of the poverty variable; the control group ($M = 0.1008$, $SD = 0.3952$) was outperformed by the target group ($M = -0.1320$, $SD = 0.3863$); $t(55) = 2.138$, $p = 0.037$.

Even though the difference between the control and target group is statistically significant for several of the variables, the target group outperformed the control group for every variable except unemployment in Alameda County (Table 7).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------|---------------------|---------|--------|--------------|-----------|
| Alameda County | Target | Target | Target | Control | Target |
| San Francisco County | Target | Target | Target | Target | Target |
| San Francisco MSA | Target | Target | Target | Target | Target |

Table 6. San Francisco MSA Overall Performance

The socioeconomic index and poverty improved in the target group for both counties and the MSA but not in the control group. Income only improved in the target group in Alameda County from 1990 to 2005–2009. Unemployment improved only in the control group in Alameda County and the target group in San Francisco County. Education improved in both the control and target groups in San Francisco County but only improved in the target group in Alameda County and the San Francisco MSA (Table 8).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------|---------------------|---------|---------|--------------|-----------|
| Alameda County | Target | Target | Target | Control | Target |
| San Francisco County | Target | Target | Neither | Target | Both |
| San Francisco MSA | Target | Target | Neither | Neither | Target |

Table 7. San Francisco MSA Improvement

No counties had a large enough sample size to be examined independently in the Riverside MSA. The Independent Sample T-tests indicate that the significance of the difference between the means for the control and target groups is not statistically different for the socioeconomic index or any of the variables in the Riverside MSA (Table 9).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Riverside MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 8. Riverside MSA Independent Sample T-tests Results

Even though the difference between the control and target group is not statistically significant for the socioeconomic index or any of the variables, the control group outperformed the target group for every variable except unemployment in the Riverside MSA (Table 10).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| Riverside MSA | Control | Control | Control | Target | Control |

Table 9. Riverside MSA Overall Performance

The poverty and unemployment variable did not improve in either the control or target group in the Riverside MSA from 1990 to 2005–2009. However, the socioeconomic index, income, and education variable did improve in the control group (Table 11).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| Riverside MSA | Control | Neither | Control | Neither | Control |

Table 10. Riverside MSA Improvement

No counties had a large enough sample size to be examined independently in the Seattle MSA. The Independent Sample T-tests indicate that the significance of the difference between the means for the control and target groups is only statistically significant for the income variable (Table 12).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-------------|-----------------|-----------------|
| Seattle MSA | Not Significant | Not Significant | Significant | Not Significant | Not Significant |

Table 11. Seattle MSA Independent Sample T-tests Results

In the Seattle MSA, there is a significant difference in the performance of the income variable; the control group ($M = 0.4633$, $SD = 0.6988$) was outperformed by the target group ($M = -0.1771$, $SD = 0.1680$); $t(11) = 2.363$, $p = 0.038$.

Even though the difference between the control and target groups is only statistically significant for the income variable, the target group outperformed the control group for every variable except education in the Seattle MSA (Table 13).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------|---------------------|---------|--------|--------------|-----------|
| Seattle MSA | Target | Target | Target | Target | Control |

Table 12. Seattle MSA Overall Performance

What is interesting to note about the Seattle MSA is that all the variables improved in the target group from 1990 to 2005–2009, including the socioeconomic index. The only variable that improved in the control group was education (Table 14).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------|---------------------|---------|--------|--------------|-----------|
| Seattle MSA | Target | Target | Target | Target | Both |

Table 13. Seattle MSA Improvement

One county in the San Diego MSA – San Diego County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is not statistically significant for the socioeconomic index or any of the variables for San Diego County and San Diego MSA (Table 15).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| San Diego County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| San Diego MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 14. San Diego MSA Independent Sample T-tests Results

However, even though the difference between the control and target groups is not statistically significant for the socioeconomic index or any of the variables, the target group outperformed the control group for every variable in both San Diego County and the San Diego MSA (Table 16).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|------------------|---------------------|---------|--------|--------------|-----------|
| San Diego County | Target | Target | Target | Target | Target |
| San Diego MSA | Target | Target | Target | Target | Target |

Table 15. San Diego MSA Overall Performance

All the variables in San Diego County and the San Diego MSA improved in the target group from 1990 to 2005–2009 except for income. The only variable that improved in the control group was education (Table 17).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|------------------|---------------------|---------|---------|--------------|-----------|
| San Diego County | Target | Target | Neither | Target | Both |
| San Diego MSA | Target | Target | Neither | Target | Both |

Table 16. San Diego MSA Improvement

Taking into consideration all five MSAs studied in the Western Region, the Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for the socioeconomic index and all the variables except unemployment (Table 18).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-------------|-------------|-----------------|-------------|
| Western Region | Significant | Significant | Significant | Not Significant | Significant |

Table 17. Western Region Independent Sample T-tests Results

In the Western Region, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9408$, $SD = 0.3554$) was outperformed by the target group ($M = 0.6088$, $SD = 0.2468$); $t(309.294) = 9.989$, $p = 0.000$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.2929$, $SD = 1.5402$) was outperformed by the target group ($M = 0.0175$, $SD = 0.4097$); $t(269.559) = 2.481$, $p = 0.014$. There is a significant difference in the performance of the income variable; the control group ($M = -0.0060$, $SD = 0.5109$) was outperformed by the target group ($M = -0.5818$, $SD = 0.4792$); $t(332) = 10.015$, $p = 0.000$. There is a

significant difference in the performance of the education variable; the control group ($M = -0.0978$, $SD = 0.5180$) was outperformed by the target group ($M = -0.2858$, $SD = 0.3821$); $t(332) = 3.442$, $p = 0.001$.

In the Western Region, the target group outperformed the control group in the socioeconomic index. Also, the target group outperformed the control group in every variable in the Western Region for every (Table 19).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------|---------------------|---------|--------|--------------|-----------|
| Western Region | Target | Target | Target | Target | Target |

Table 18. Western Region Overall Performance

The socioeconomic index, income, and education improved in both the control and target group from 1990 to 2005–2009 in the Western Region. Unemployment improved in the target group and the only variable that did not improve in either group was poverty (Table 20).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------|---------------------|---------|--------|--------------|-----------|
| Western Region | Both | Neither | Both | Target | Both |

Table 19. Western Region Improvement

4.2 Southwestern Region

Three MSAs in the Southwestern Region of the United States were examined for this study: Dallas-Fort Worth-Arlington, TX (Dallas MSA), Houston-Sugar Land-Baytown, TX (Houston MSA), and Phoenix-Mesa-Glendale, AZ (Phoenix MSA).

Two counties in the Dallas MSA – Tarrant County and Dallas County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is

statistically different for the socioeconomic index, poverty, income, and education in Dallas County and the Dallas MSA (Table 21).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Dallas County | Significant | Significant | Significant | Not Significant | Significant |
| Tarrant County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Dallas MSA | Significant | Significant | Significant | Not Significant | Significant |

Table 20. Dallas MSA Independent Sample T-tests Results

In Dallas County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9762$, $SD = 0.4872$) outperformed the target group ($M = 1.1891$, $SD = 0.4399$); $t(97) = -2.206$, $p = 0.030$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.1129$, $SD = 0.5064$) outperformed the target group ($M = 0.4909$, $SD = 0.6817$); $t(64.783) = -2.971$, $p = 0.004$. There is a significant difference in the performance of the income variable; the control group ($M = -0.1015$, $SD = 0.3636$) outperformed the target group ($M = 0.2992$, $SD = 1.4935$); $t(97) = -1.994$, $p = 0.049$. There is also a significant difference in the performance of the education variable; the control group ($M = -0.0534$, $SD = 0.3363$) outperformed the target group ($M = 0.2666$, $SD = 0.7676$); $t(47.598) = -2.455$, $p = 0.018$.

In the Dallas MSA, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9742$, $SD = 0.4046$) outperformed the target group ($M = 1.1390$, $SD = 0.4179$); $t(167) = -2.537$, $p = 0.012$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.1346$, $SD = 0.5756$) outperformed the target group ($M = 0.3608$, $SD = 0.6398$); $t(167) = -2.375$, $p = 0.019$. There is a significant difference in the performance of the income variable; the

control group ($M = -0.0419$, $SD = 0.3580$) outperformed the target group ($M = 0.2358$, $SD = 1.1754$); $t(167) = -2.259$, $p = 0.025$. There is also a significant difference in the performance of the education variable; the control group ($M = -0.0596$, $SD = 0.3465$) outperformed the target group ($M = 0.1292$, $SD = 0.6827$); $t(83.099) = -2.057$, $p = 0.043$.

The control group outperformed the target group on almost every account except for the unemployment variable in Dallas County and the MSA, which was contrary to the performance of many other MSAs in this study (Table 22).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------|---------------------|---------|---------|--------------|-----------|
| Dallas County | Control | Control | Control | Target | Control |
| Tarrant County | Control | Control | Control | Control | Control |
| Dallas MSA | Control | Control | Control | Target | Control |

Table 22. Dallas MSA Overall Performance

None of the variables in the Dallas MSA improved from 1990 to 2005–2009 in the target group. The only variables that improved were in the control group and included income in both Dallas County and the Dallas MSA, unemployment in Tarrant County, and education in both counties and the Dallas MSA. The socioeconomic index also improved in both counties and the Dallas MSA (Table 23).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------|---------------------|---------|---------|--------------|-----------|
| Dallas County | Control | Neither | Control | Neither | Control |
| Tarrant County | Control | Neither | Neither | Control | Control |
| Dallas MSA | Control | Neither | Control | Neither | Control |

Table 21. Dallas MSA Improvement

One county in the Houston MSA – Harris County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant

for the income variable in both Harris County and the Houston MSA and the socioeconomic index in Harris County (Table 24).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-------------|-----------------|-----------------|
| Harris County | Significant | Not Significant | Significant | Not Significant | Not Significant |
| Houston MSA | Not Significant | Not Significant | Significant | Not Significant | Not Significant |

Table 22. Houston MSA Independent Sample T-tests Results

In Harris County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9248$, $SD = 0.3476$) outperformed the target group ($M = 1.0670$, $SD = 0.3512$); $t(124) = -2.052$, $p = 0.042$. There is also a significant difference in the performance of the income variable; the control group ($M = -0.0116$, $SD = 0.3047$) outperformed the target group ($M = 0.1249$, $SD = 0.3231$); $t(124) = -2.215$, $p = 0.029$.

In the Houston MSA, there is a significant difference in the performance of the income variable; the control group ($M = -0.0065$, $SD = 0.2987$) outperformed the target group ($M = 0.1169$, $SD = 0.3067$); $t(134) = -2.179$, $p = 0.031$.

Even though the difference between the control and target group is not statistically significant for many of the variables in Harris County or the Houston MSA, the control group outperformed the target group on every account. This is consistent with the performance of the Dallas MSA; however, this is contrary to the performance of many other MSAs in this study (Table 25).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| Harris County | Control | Control | Control | Control | Control |
| Houston MSA | Control | Control | Control | Control | Control |

Table 23. Houston MSA Overall Performance

None of the variables in the target group improved from 1990 to 2005–2009. All of the variables improved in the control group except for poverty in Harris County and the Houston MSA (Table 26).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| Harris County | Control | Neither | Control | Control | Control |
| Houston MSA | Control | Neither | Control | Control | Control |

Table 24. Houston MSA Improvement

One county in the Phoenix MSA – Maricopa County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is only statistically significant for the income variable in both Maricopa County and the Phoenix MSA (Table 27).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-------------|-----------------|-----------------|
| Maricopa County | Not Significant | Not Significant | Significant | Not Significant | Not Significant |
| Phoenix MSA | Not Significant | Not Significant | Significant | Not Significant | Not Significant |

Table 25. Phoenix MSA Independent Sample T-tests Results

In Maricopa County, there is a significant difference in the performance of the income variable; the control group ($M = 0.0395$, $SD = 0.4500$) was outperformed by the target group ($M = -0.1955$, $SD = 0.4722$); $t(81) = 2.101$, $p = 0.039$. In the Phoenix MSA, there is a significant difference in the performance of the income variable; the control

group ($M = 0.0413$, $SD = 0.4482$) was outperformed by the target group ($M = -0.1666$, $SD = 0.4481$); $t(89) = 2.022$, $p = 0.046$.

Even though the difference between the control and target group is only statistically significant for one of the variables in Maricopa County and the Phoenix MSA, the target group overwhelmingly outperformed the control group for every variable except unemployment. This is not consistent with the performance of the Dallas MSA and Houston MSA; however, it is consistent with the performance of many other MSAs throughout the country (Table 28).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-----------------|---------------------|---------|--------|--------------|-----------|
| Maricopa County | Target | Target | Target | Control | Target |
| Phoenix MSA | Target | Target | Target | Control | Target |

Table 26. Phoenix MSA Overall Performance

Poverty did not improve from 1990 to 2005–2009 in Maricopa County or the Phoenix MSA. The socioeconomic index, income, and education improved in the target group in Maricopa County and the Phoenix MSA. Unemployment improved in the control group only in Maricopa County and the Phoenix MSA (Table 29).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-----------------|---------------------|---------|--------|--------------|-----------|
| Maricopa County | Target | Neither | Target | Control | Target |
| Phoenix MSA | Target | Neither | Target | Control | Target |

Table 27. Phoenix MSA Improvement

When evaluating all three MSAs studied in the Southwest, the Independent Sample T-tests indicate that the difference between the means for the control and target groups is only statistically significant for the socioeconomic index and income variable (Table 30).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-------------|-----------------|-----------------|
| Southwestern Region | Significant | Not Significant | Significant | Not Significant | Not Significant |

Table 28. Southwestern Region Independent Sample T-tests Results

In the Southwestern Region, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9667$, $SD = 0.3767$) outperformed the target group ($M = 1.0532$, $SD = 0.4002$); $t(394) = -2.108$, $p = 0.036$. There is a significant difference in the performance of the income variable; the control group ($M = -0.0090$, $SD = 0.3628$) outperformed the target group ($M = 0.1166$, $SD = 0.8726$); $t(394) = -2.018$, $p = 0.044$.

The control group outperformed the target group for the socioeconomic index, poverty, income, and education. The target group outperformed the control group for unemployment (Table 31).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|---------|--------------|-----------|
| Southwestern Region | Control | Control | Control | Target | Control |

Table 29. Southwestern Region Overall Performance

The socioeconomic index, income, and education were the only variables that improved from 1990 to 2005–2009 in the control group. The remaining variables did not improve in either group (Table 32).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|---------|--------------|-----------|
| Southwestern Region | Control | Neither | Control | Neither | Control |

Table 30. Southwestern Region Improvement

4.3 Midwestern Region

Four MSAs in the Midwestern Region of the United States were examined for this study: Chicago-Joliet-Naperville, IL-IN-WI (Chicago MSA), Detroit-Warren-Livonia, MI (Detroit MSA), Minneapolis-St. Paul-Bloomington, MN-WI (Minneapolis MSA), and St. Louis, MO-IL (St. Louis MSA).

One county in the Chicago MSA – Cook County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for the socioeconomic index, poverty and income in Cook County and the Chicago MSA (Table 33).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-------------|-------------|-----------------|-----------------|
| Cook County | Significant | Significant | Significant | Not Significant | Not Significant |
| Chicago MSA | Significant | Significant | Significant | Not Significant | Not Significant |

Table 31. Chicago MSA Independent Sample T-tests Results

In Cook County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.8427$, $SD = 0.3243$) was outperformed by the target group ($M = 0.7496$, $SD = 0.2688$); $t(186.224) = 2.700$, $p = 0.008$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.0997$, $SD = 0.8161$) was outperformed by the target group ($M = -0.1010$, $SD = 0.3640$); $t(332.146) = 3.189$, $p = 0.002$. There is also a significant difference in the performance of the income variable; the control group ($M = 0.0170$, $SD = 0.4565$) was outperformed by the target group ($M = -0.1218$, $SD = 0.4255$); $t(355) = 2.546$, $p = 0.011$.

In the Chicago MSA, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.8494$, $SD = 0.3300$) was outperformed by the target group ($M = 0.7610$, $SD = 0.2737$); $t(366) = 2.346$, $p = 0.020$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.1010$, $SD = 0.8073$) was outperformed by the target group ($M = -0.0924$, $SD = 0.3587$); $t(345.949) = 3.162$, $p = 0.002$. There is also a significant difference in the performance of the income variable; the control group ($M = 0.0163$, $SD = 0.4560$) was outperformed by the target group ($M = -0.1196$, $SD = 0.4181$); $t(366) = 2.554$, $p = 0.011$.

The target group outperformed the control group for every variable except unemployment in Cook County and the Chicago MSA (Table 34).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------|---------------------|---------|--------|--------------|-----------|
| Cook County | Target | Target | Target | Control | Target |
| Chicago MSA | Target | Target | Target | Control | Target |

Table 32. Chicago MSA Overall Performance

The socioeconomic index and education variable improved from 1990 to 2005–2009 for both the control and target groups in Cook County and the Chicago MSA. The target group also improved in poverty and income. Unemployment improved only in the control group in Cook County (Table 35).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------|---------------------|---------|--------|--------------|-----------|
| Cook County | Both | Target | Target | Control | Both |
| Chicago MSA | Both | Target | Target | Neither | Both |

Table 33. Chicago MSA Improvement

One county in the Detroit MSA – Wayne County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the

difference between the means for the control and target group is not statistically significant for any of the variables in Wayne County or the Detroit MSA (Table 36).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Wayne County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Detroit MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 34. Detroit MSA Independent Sample T-tests Results

Even though the difference between the control and target groups is not statistically significant for any of the variables in Wayne County and the Detroit MSA, the control group overwhelmingly outperformed the target group for every variable. This finding is consistent with the Dallas MSA, Houston MSA, and Riverside MSA, but this result is unusual compared to the rest of the MSAs studied (Table 37).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|--------------|---------------------|---------|---------|--------------|-----------|
| Wayne County | Control | Control | Control | Control | Control |
| Detroit MSA | Control | Control | Control | Control | Control |

Table 35. Detroit MSA Overall Performance

The socioeconomic index, income, and education variable improved from 1990 to 2005–2009 for both the control and target group in Wayne County and the Detroit MSA. Unemployment and poverty did not improve in either group (Table 38).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|--------------|---------------------|---------|--------|--------------|-----------|
| Wayne County | Both | Neither | Both | Neither | Both |
| Detroit MSA | Both | Neither | Both | Neither | Both |

Table 36. Detroit MSA Improvement

No counties in the Minneapolis MSA had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference

between the means for the control and target group is not statistically significant for any of the variables in the Minneapolis MSA (Table 39).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Minneapolis MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 37. Minneapolis MSA Independent Sample T-tests Results

Even though the difference between the control and target groups is not statistically significant for any of the variables in the Minneapolis MSA, the target group outperformed the control group for every variable except unemployment (Table 40).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-----------------|---------------------|---------|--------|--------------|-----------|
| Minneapolis MSA | Target | Target | Target | Control | Target |

Table 38. Minneapolis MSA Overall Performance

The only variable that improved from 1990 to 2005–2009 for the control and target group in the Minneapolis MSA was education. The socioeconomic index also improved but only for the target group. The remaining variables did not improve in the control or target group (Table 41).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-----------------|---------------------|---------|---------|--------------|-----------|
| Minneapolis MSA | Target | Neither | Neither | Neither | Both |

Table 39. Minneapolis MSA Improvement

No counties in the St. Louis MSA had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target group is not statistically significant for the socioeconomic index or any of the variables (Table 42).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| St. Louis MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 40. St. Louis MSA Independent Sample T-tests Results

Even though the difference between the control and target groups is not statistically significant for the socioeconomic index or any of the variables, the target group outperformed the control group for all of the variables except education (Table 43).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|--------|--------------|-----------|
| St. Louis MSA | Target | Target | Target | Target | Control |

Table 41. St. Louis MSA Overall Performance

The only variable that improved from 1990 to 2005–2009 for both the control and target group in the St. Louis MSA was education. The socioeconomic index improved in the target group and the remaining variables did not improve in the control or target group (Table 44).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| St. Louis MSA | Target | Neither | Neither | Neither | Both |

Table 42. St. Louis MSA Improvement

When evaluating all four MSAs studied in the Midwest, the Independent Sample T-tests indicate that the difference between the means for the control and target group is statistically significant for the poverty variable (Table 45).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-------------|-----------------|-----------------|-----------------|
| Midwestern Region | Not Significant | Significant | Not Significant | Not Significant | Not Significant |

Table 43. Midwestern Region Independent Sample T-tests Results

In the Midwestern Region, there is a significant difference in the performance of the poverty variable; the control group ($M = 0.1332$, $SD = 0.7259$) was outperformed by the target group ($M = 0.0330$, $SD = 0.4041$); $t(638.458) = 2.270$, $p = 0.024$.

Even though the difference between the control and target groups is only statistically significant for poverty, the target group outperformed the control group for all of the other variables except unemployment (Table 46).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------------|---------------------|---------|--------|--------------|-----------|
| Midwestern Region | Target | Target | Target | Control | Target |

Table 44. Midwestern Region Overall Performance

The socioeconomic index, income, and education improved from 1990 to 2005–2009 for both the control and target groups in the Midwest. Poverty and unemployment did not improve in the control or target group (Table 47).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------------|---------------------|---------|--------|--------------|-----------|
| Midwestern Region | Both | Neither | Both | Neither | Both |

Table 45. Midwestern Region Improvement

4.4 Northeastern Region

Five MSAs in the Northeastern Region of the United States were examined for this study: New York-Northern New Jersey-Long Island, NY-NJ-PA (New York MSA), Philadelphia-Camden-Wilmington, PA-NJ-DE-MD (Philadelphia MSA), Washington-Arlington-Alexandria, DC-VA-MD-WV (Washington D.C. MSA), Boston-Cambridge-Quincy, MA-NH (Boston MSA), and Baltimore-Towson, MD (Baltimore MSA).

Six counties in the New York MSA – Essex County, Passaic County, Union County, Bronx County, Kings County, and New York County – had a large enough

sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for the socioeconomic index, poverty, and income in Bronx County, the socioeconomic index, poverty, and education in Kings County, the socioeconomic index and income in New York County, and for all the variables in the New York MSA (Table 48).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Essex County, NJ | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Passaic County, NJ | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Union County, NJ | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Bronx County, NY | Significant | Significant | Significant | Not Significant | Not Significant |
| Kings County, NY | Significant | Significant | Not Significant | Not Significant | Significant |
| New York County, NY | Significant | Not Significant | Significant | Not Significant | Not Significant |
| New York MSA | Significant | Significant | Significant | Significant | Significant |

Table 46. New York MSA Independent Sample T-tests Results

In Bronx County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9426$, $SD = 0.2673$) was outperformed by the target group ($M = 0.8126$, $SD = 0.1547$); $t(93.006) = 3.447$, $p = 0.001$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.1682$, $SD = 0.5606$) was outperformed by the target group ($M = -0.0896$, $SD = 0.2608$); $t(82.363) = 3.383$, $p = 0.001$. There is also a significant difference in the performance of the income variable; the control group ($M = 0.1802$, $SD = 1.1321$) was outperformed by the target group ($M = -0.1228$, $SD = 0.2312$); $t(65.937) = 2.091$, $p = 0.040$.

In Kings County, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.8628$, $SD = 0.2491$) was outperformed by the target group ($M = 0.7471$, $SD = 0.2538$); $t(251) = 3.568$, $p = 0.000$. There is a significant difference in the performance of the poverty variable; the control group ($M = 0.1575$, $SD = 0.7816$) was outperformed by the target group ($M = -0.1507$, $SD = 0.2852$); $t(212.740) = 4.470$, $p = 0.000$. There is also a significant difference in the performance of the education variable; the control group ($M = -0.3194$, $SD = 0.2273$) was outperformed by the target group ($M = -0.4118$, $SD = 0.1858$); $t(251) = 3.363$, $p = 0.001$.

In New York County, there is a significant different in the performance of the socioeconomic index; the control group ($M = 0.9627$, $SD = 0.2312$) was outperformed by the target group ($M = 0.7992$, $SD = 0.2561$); $t(85) = 2.730$, $p = 0.008$. There is also a significant different in the performance of the income variable; the control group ($M = 0.2928$, $SD = 0.3095$) was outperformed by the target group ($M = 0.0320$, $SD = 0.3738$); $t(85) = 3.041$, $p = 0.003$.

In the New York MSA, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9090$, $SD = 0.2506$) was outperformed by the target group ($M = 0.8045$, $SD = 0.2347$); $t(690) = 5.578$, $p = 0.000$. There is a significant difference in the poverty variable; the control group ($M = 0.1934$, $SD = 0.6817$) was outperformed by the target group ($M = -0.0749$, $SD = 0.5538$); $t(685.199) = 5.707$, $p = 0.000$. There is a significant difference in the income variable; the control group ($M = 0.1042$, $SD = 0.5370$) was outperformed by the target group ($M = -0.0159$, $SD = 0.7128$); $t(690) = 2.528$, $p = 0.012$. There is a significant difference in the unemployment variable; the control group ($M = -0.0173$, $SD = 0.8040$) was outperformed

by the target group ($M = -0.1273$, $SD = 0.5871$); $t(689.645) = 2.082$, $p = 0.038$. Last, there is a significant difference in the education variable; the control group ($M = -0.2953$, $SD = 0.2391$) was outperformed by the target group ($M = -0.3413$, $SD = 0.2290$); $t(690) = 2.548$, $p = 0.011$.

The target group overwhelmingly outperformed the control group in most of the counties and in the New York MSA as a whole. The only counties in which the control group outperformed the target group were Essex County for the socioeconomic index, unemployment, and the education variables; Passaic County for the socioeconomic index, income, and unemployment variables; and Union County for the education variable (Table 49).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|---------|--------------|-----------|
| Essex County, NJ | Control | Target | Target | Control | Control |
| Passaic County, NJ | Control | Target | Control | Control | Target |
| Union County, NJ | Target | Target | Target | Target | Control |
| Bronx County, NY | Target | Target | Target | Target | Target |
| Kings County, NY | Target | Target | Target | Target | Target |
| New York County, NY | Target | Target | Target | Target | Target |
| New York MSA | Target | Target | Target | Target | Target |

Table 47. New York MSA Overall Performance

The socioeconomic index and education variable improved in both the control and target group across each county and the entire MSA. Poverty improved in the target group in Essex County, Bronx County, Kings County, and the New York MSA and in both the control and target group in New York County. Income improved in the target group in Bronx County and the New York MSA, and in both the control and target group in Essex County. Unemployment improved in the target group in Union County and New York County, and in both the control and target group in Bronx County, Kings County,

and the New York MSA. Unemployment also improved in the control group in Passaic County, which was the only occurrence of the control group improving without the target group in all the counties and entire MSA in New York (Table 50).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|---------|--------------|-----------|
| Essex County, NJ | Both | Target | Both | Neither | Both |
| Passaic County, NJ | Both | Neither | Neither | Control | Both |
| Union County, NJ | Both | Neither | Neither | Target | Both |
| Bronx County, NY | Both | Target | Target | Both | Both |
| Kings County, NY | Both | Target | Neither | Both | Both |
| New York County, NY | Both | Both | Neither | Target | Both |
| New York MSA | Both | Target | Target | Both | Both |

Table 48. New York MSA Improvement

One county in the Philadelphia MSA – Philadelphia County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for poverty in Philadelphia County and the Philadelphia MSA (Table 51).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-------------|-----------------|-----------------|-----------------|
| Philadelphia County | Not Significant | Significant | Not Significant | Not Significant | Not Significant |
| Philadelphia MSA | Not Significant | Significant | Not Significant | Not Significant | Not Significant |

Table 49. Philadelphia MSA Independent Sample T-tests Results

In Philadelphia County, there is a significant difference in the performance of the poverty variable; the control group ($M = 0.5480$, $SD = 0.8174$) was outperformed by the target group ($M = 0.1824$, $SD = 0.5448$); $t(83.412) = 2.613$, $p = 0.011$.

In the Philadelphia MSA, there is a significant difference in the performance of the poverty variable; the control group ($M = 0.4884$, $SD = 0.7516$) was outperformed by the target group ($M = 0.2209$, $SD = 0.5204$); $t(135.157) = 2.475$, $p = 0.015$.

The target group outperformed the control group in every account in Philadelphia County except in education. In the Philadelphia MSA, the target group outperformed the control group for every variable (Table 52).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|--------|--------------|-----------|
| Philadelphia County | Target | Target | Target | Target | Control |
| Philadelphia MSA | Target | Target | Target | Target | Target |

Table 50. Philadelphia MSA Overall Performance

The socioeconomic index improved in the target group in Philadelphia County and the Philadelphia MSA. Education improved in Philadelphia County and the Philadelphia MSA in both the control and target groups. None of the other variables improved in either group (Table 53).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|---------|--------------|-----------|
| Philadelphia County | Target | Neither | Neither | Neither | Both |
| Philadelphia MSA | Target | Neither | Neither | Neither | Both |

Table 51. Philadelphia MSA Improvement

The District of Columbia was the only area that had a large enough sample size to be examined independently in the Washington D.C. MSA. The Independent Sample T-tests indicate that there is no significance in the difference between the means for the control and target groups (Table 54).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| District of Columbia | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Washington D.C. MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 52. Washington D.C. MSA Independent Sample T-tests Results

Even though the difference between the control and target groups is not statistically significant for any of the variables in the District of Columbia or Washington D.C. MSA, the target group outperformed the control group on every account (Table 55).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------|---------------------|---------|--------|--------------|-----------|
| District of Columbia | Target | Target | Target | Target | Target |
| Washington D.C. MSA | Target | Target | Target | Target | Target |

Table 53. Washington D.C. MSA Overall Performance

The only variable that improved in the District of Columbia and Washington D.C. MSA was education. Education improved in both the control and target group (Table 56).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------|---------------------|---------|---------|--------------|-----------|
| District of Columbia | Neither | Neither | Neither | Neither | Both |
| Washington D.C. MSA | Neither | Neither | Neither | Neither | Both |

Table 54. Washington D.C. MSA Improvement

Two counties in the Boston MSA – Essex County and Suffolk County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for education in Essex County and the Boston MSA (Table 57).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Essex County | Not Significant | Not Significant | Not Significant | Not Significant | Significant |
| Suffolk County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Boston MSA | Not Significant | Not Significant | Not Significant | Not Significant | Significant |

Table 55. Boston MSA Independent Sample T-tests Results

In Essex County, there is a significant difference in the performance of the education variable; the control group ($M = -0.0610$, $SD = 0.2301$) was outperformed by the target group ($M = -0.3461$, $SD = 0.1470$); $t(17) = 2.930$, $p = 0.009$.

In the Boston MSA, there is a significant difference in the performance of the education variable; the control group ($M = -0.1351$, $SD = 0.3824$) was outperformed by the target group ($M = -0.3086$, $SD = 0.2266$); $t(87) = 2.546$, $p = 0.013$.

The target group outperformed the control group for the socioeconomic index, poverty, and education in both counties and the Boston MSA. In Essex County, the target group also outperformed the control group for income and unemployment. The control group only outperformed the target group in Suffolk County and the Boston MSA in income and unemployment (Table 58).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------|---------------------|---------|---------|--------------|-----------|
| Essex County | Target | Target | Target | Target | Target |
| Suffolk County | Target | Target | Control | Control | Target |
| Boston MSA | Target | Target | Control | Control | Target |

Table 56. Boston MSA Overall Performance

In Essex County, the control and target group improved from 1990 to 2005–2009 for the socioeconomic index, unemployment, and education. Income improved in the target group only and poverty did not improve in either group in Essex County. In Suffolk County, the socioeconomic index improved in the target group, education improved in both the target and control groups, and unemployment improved in the control group. In the Boston MSA, the socioeconomic index and education variable improved in both the target and control group and unemployment improved in the control group only (Table 59).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------|---------------------|---------|---------|--------------|-----------|
| Essex County | Both | Neither | Target | Both | Both |
| Suffolk County | Target | Neither | Neither | Control | Both |
| Boston MSA | Both | Neither | Neither | Control | Both |

Table 57. Boston MSA Improvement

No counties in the Baltimore MSA had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is not statistically different for any of the variables in the Baltimore MSA (Table 60).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Baltimore MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 58. Baltimore MSA Independent Sample T-tests Results

Even though the difference between the control and target groups is not statistically significant for any of the variables in the Baltimore MSA, the target group outperformed the control group on every account except for income (Table 61).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| Baltimore MSA | Target | Target | Control | Target | Target |

Table 59. Baltimore MSA Overall Performance

The socioeconomic index improved from 1990 to 2005–2009 for both groups in the Baltimore MSA. Income improved in the control group only, and education improved in both the control and target groups in the Baltimore MSA. Poverty and unemployment did not improve in either group (Table 62).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------|---------------------|---------|---------|--------------|-----------|
| Baltimore MSA | Both | Neither | Control | Neither | Both |

Table 60. Baltimore MSA Improvement

When evaluating all five MSAs studied in the Northeast Region, the Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for all of the variables (Table 63).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-------------|-------------|--------------|-------------|
| Northeastern Region | Significant | Significant | Significant | Significant | Significant |

Table 61. Northeastern Region Independent Sample T-tests Results

In the Northeast, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9586$, $SD = 0.2966$) was outperformed by the target group ($M = 0.8697$, $SD = 0.2710$); $t(1084) = 5.069$, $p = 0.000$. There is a significant difference in the poverty variable; the control group ($M = 0.2482$, $SD = 0.7124$) was outperformed by the target group ($M = 0.0110$, $SD = 0.5367$); $t(1083.891) = 6.258$, $p = 0.000$. There is a significant difference in the income variable; the control group ($M = 0.1452$, $SD = 0.5445$) was outperformed by the target group ($M = 0.0706$, $SD = 0.6510$); $t(1084) = 2.053$, $p = 0.040$. There is a significant difference in the unemployment variable; the control group ($M = 0.1600$, $SD = 1.0528$) was outperformed by the target group ($M = 0.0173$, $SD = 0.7263$); $t(1077.763) = 2.642$, $p = 0.008$. Last, there is a significant difference in the education variable; the control group ($M = -0.2987$, $SD = 0.2619$) was outperformed by the target group ($M = -0.3429$, $SD = 0.2305$); $t(1084) = 2.898$, $p = 0.004$.

As stated above, the target group outperformed the control group on every account in the Northeastern Region. Not only did the target group outperform the control group in the socioeconomic index, but also in every variable including poverty, income, unemployment, and education (Table 64).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|--------|--------------|-----------|
| Northeastern Region | Target | Target | Target | Target | Target |

Table 62. Northeastern Region Overall Performance

The socioeconomic index and education improved from 1990 to 2005–2009 in both the control and target groups in the Northeast. Poverty, income, and unemployment did not improve in either group in the Northeast (Table 65).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|---------------------|---------------------|---------|---------|--------------|-----------|
| Northeastern Region | Both | Neither | Neither | Neither | Both |

Table 63. Northeastern Region Improvement

4.5 Southeastern Region

The three largest urban areas in the Southeastern Region of the United States examined were Miami-Fort Lauderdale-Pompano Beach, FL MSA (Miami MSA), Atlanta-Sandy Springs-Marietta, GA MSA (Atlanta MSA), and Tampa-St. Petersburg-Clearwater, FL, MSA (Tampa MSA).

Three counties in the Miami MSA – Broward County, Miami-Dade County, and Palm Beach County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is not statistically significant for any of the variables in the Miami MSA (Table 66).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-----------------|-----------------|-----------------|-----------------|
| Broward County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Miami-Dade County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Palm Beach County | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |
| Miami MSA | Not Significant | Not Significant | Not Significant | Not Significant | Not Significant |

Table 64. Miami MSA Independent Sample T-tests Results

Even though the difference between the control and target groups is not statistically significant for any of the variables in the Miami MSA, the target group outperformed the control group on every account except in unemployment for Miami-Dade County (Table 67).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |

| Broward County | Target | Target | Target | Target | Target |
| Miami-Dade County | Target | Target | Target | Control | Target |
| Palm Beach County | Target | Target | Target | Target | Target |
| Miami MSA | Target | Target | Target | Target | Target |

Table 65. Miami MSA Overall Performance

The socioeconomic index improved in the target group for Miami-Dade County, Palm Beach County, and the Miami MSA. Poverty only improved in the target group in Miami-Dade County. Income and unemployment did not improve in any of the counties or the MSA in either group; however, education improved in all the counties and the Miami MSA in both groups (Table 68).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------------|---------------------|---------|---------|--------------|-----------|
| Broward County | Neither | Neither | Neither | Neither | Both |
| Miami-Dade County | Target | Target | Neither | Neither | Both |
| Palm Beach County | Target | Neither | Neither | Neither | Both |
| Miami MSA | Target | Neither | Neither | Neither | Both |

Table 66. Miami MSA Improvement

One county in the Atlanta MSA – Fulton County – had a large enough sample size to be examined independently. The Independent Sample T-tests indicate that the difference between the means for the control and target groups is not statistically significant for any of the variables in the Atlanta MSA (Table 69).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |

Table 75. Southeastern Region Improvement

4.6 All MSAs

When examining all twenty MSAs together, the Independent Sample T-tests indicate that the difference between the means for the control and target groups is statistically significant for all of the variables except unemployment (Table 78).

| Independent Sample T-tests | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|----------------------------|---------------------|-------------|-------------|-----------------|-------------|
| All MSAs | Significant | Significant | Significant | Not Significant | Significant |

Table 76. All MSAs Independent Sample T-tests Results

Taking into consideration all twenty MSAs, there is a significant difference in the performance of the socioeconomic index; the control group ($M = 0.9469$, $SD = 0.3898$) was outperformed by the target group ($M = 0.8677$, $SD = 0.3819$); $t(2753) = 5.499$, $p = 0.000$. There is a significant difference in the poverty variable; the control group ($M = 0.2404$, $SD = 1.5127$) was outperformed by the target group ($M = 0.0493$, $SD = 0.5116$); $t(2320.949) = 4.813$, $p = 0.000$. There is a significant difference in the income variable; the control group ($M = 0.0533$, $SD = 0.4690$) was outperformed by the target group ($M = -0.0259$, $SD = 0.6353$); $t(1680.606) = 3.468$, $p = 0.001$. Last, there is a significant difference in the education variable; the control group ($M = -0.2313$, $SD = 0.5023$) was outperformed by the target group ($M = -0.2858$, $SD = 0.3776$); $t(2753) = 3.005$, $p = 0.003$.

In addition to four of the five variables being statistically significant, the target group outperformed the control group on all accounts; even for the unemployment variable (Table 79).

| Performance | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------|---------------------|---------|--------|--------------|-----------|
| All MSAs | Target | Target | Target | Target | Target |

Table 77. All MSAs Overall Performance

The socioeconomic index and education improved in both the target and control groups when all twenty MSAs were examined together from 1990 to 2005–2009. Income improved for the target group only, and poverty and unemployment did not improve in either group (Table 80).

| Improvement | Socioeconomic Index | Poverty | Income | Unemployment | Education |
|-------------|---------------------|---------|--------|--------------|-----------|
| All MSAs | Both | Neither | Target | Neither | Both |

Table 78. All MSAs Improvement

4.7 Socioeconomic Index MSA Maps

To better understand the spatial distribution of target census tracts in comparison to the control group, the socioeconomic index of all the target groups were mapped against the control group mean for each MSA. This was done using census tract shapefiles in ArcGIS. The socioeconomic index for each census tract in the target group was subtracted from the entire control group's socioeconomic index mean. This was done for each of the 20 MSAs. In each figure, the target group QCTs that outperformed the control group are depicted in light gray and the target group QCTs that underperformed are depicted in dark gray. The maps for each MSA are shown at scales appropriate to present the areas most populated with target QCTs.

Figure 2 shows the performance of Los Angeles MSA census tracts in the target group in relation to the control mean. In this figure, all target QCTs outperformed the control group. Aggregations of outperforming QCTs are located in the commuter cities of Inglewood and Hawthorne, near the Port of Long Beach, and in Santa Ana. The great majority of Los Angeles QCTs are in and around the Inglewood district, an area known for poor socioeconomic conditions.

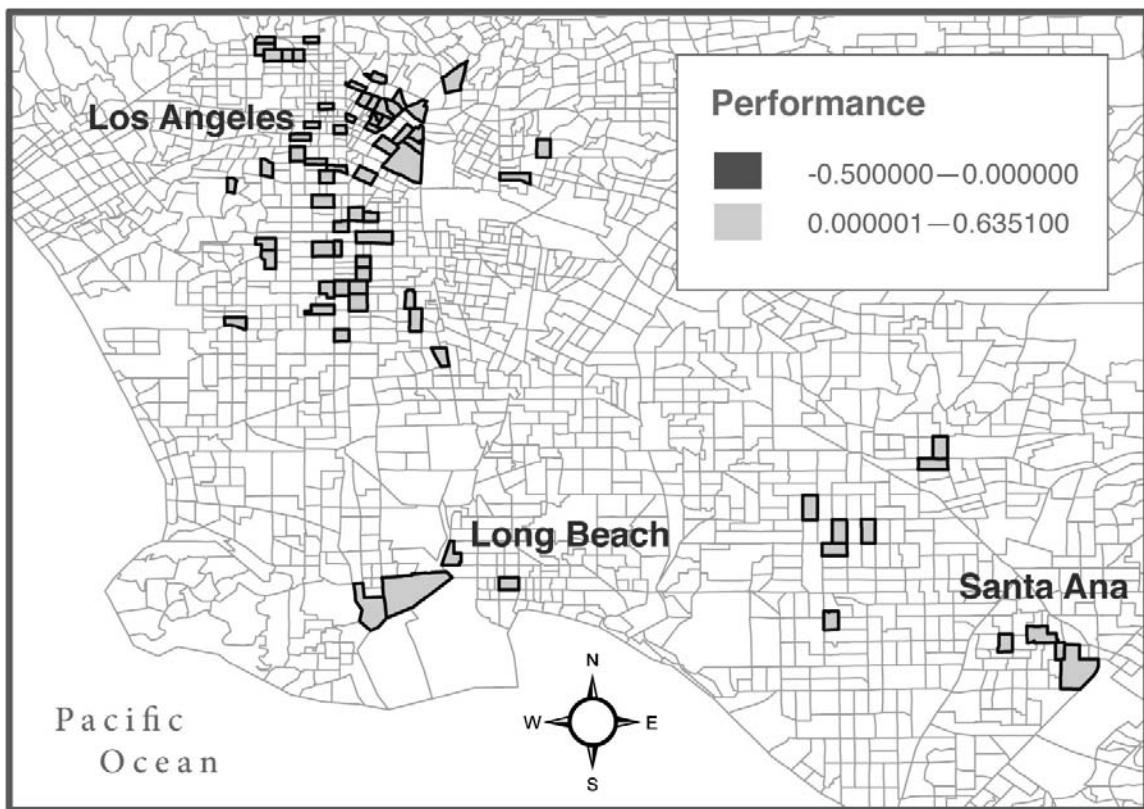

Figure 2. Los Angeles MSA Target Compared to Control Mean

Figure 3 shows the performance of San Francisco MSA census tracts in the target group in relation to the control mean. In this figure, only four QCTs underperformed the control group, including a geographically large tract near Corte Madera near San Rafael. Outperforming QCTs are largely located in downtown San Francisco and downtown Oakland, where population densities are high.

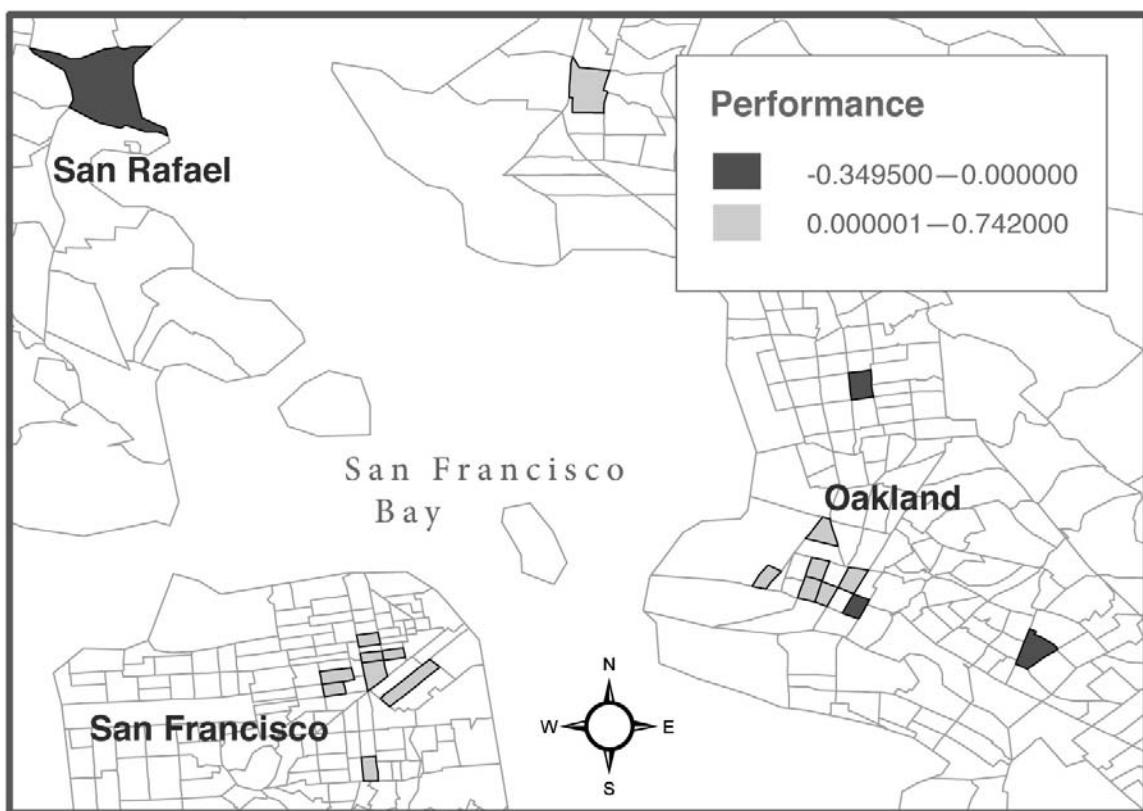

Figure 3. San Francisco MSA Target Compared to Control Mean

Figure 4 shows the performance of Riverside MSA census tracts in the target group in relation to the control mean. In this figure, only six census tracts in the MSA are QCTs and all are widely distributed, pointing to a minimal relationship between the existence of QCTs and geographic location or population density in this MSA. In this figure, there were only three target group census tracts in the Riverside MSA that outperformed the control mean.

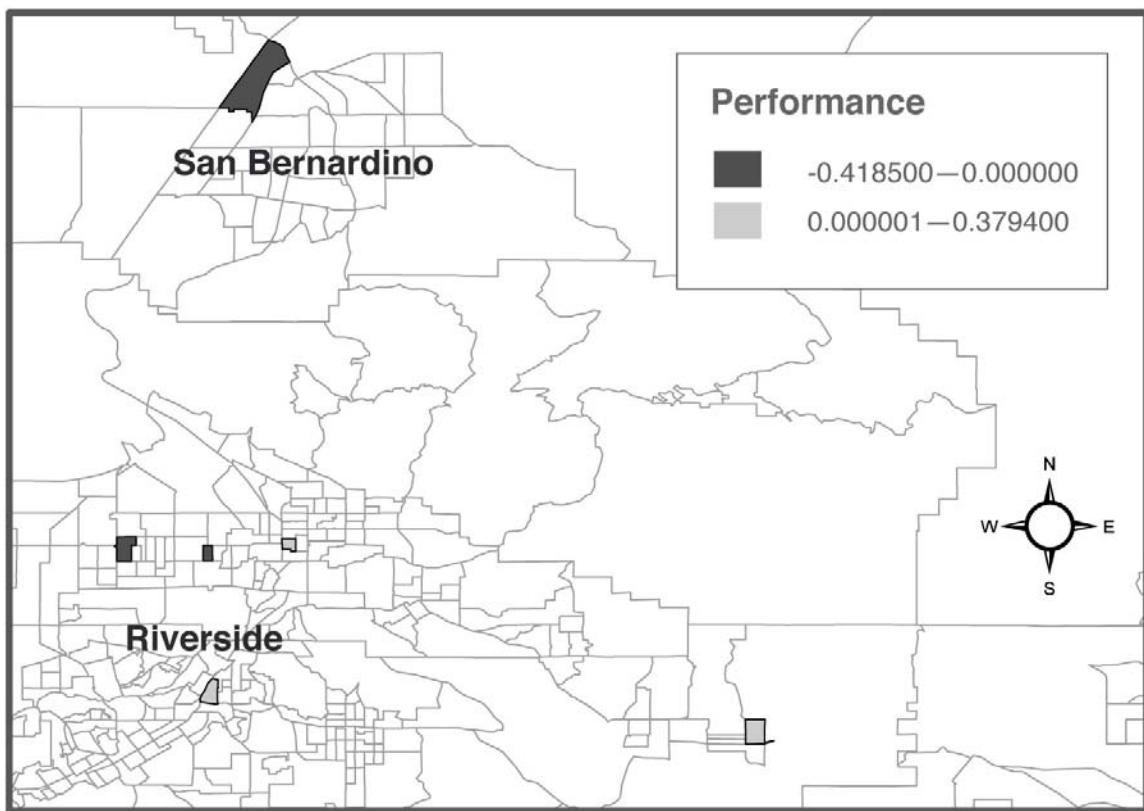

Figure 4. Riverside MSA Target Compared to Control Mean

Figure 5 shows the performance of Seattle MSA census tracts in the target group in relation to the control mean. In this figure, all QCTs outperformed the control group, and all but one is located in downtown Seattle, a densely populated center. The remaining QCT is located in Tacoma. Unfortunately, the small sample size in the Seattle MSA makes it difficult to determine if the performance of the QCTs and emerging geographic pattern is random or if an overall pattern would transpire as seen in the New York or St. Louis MSAs.

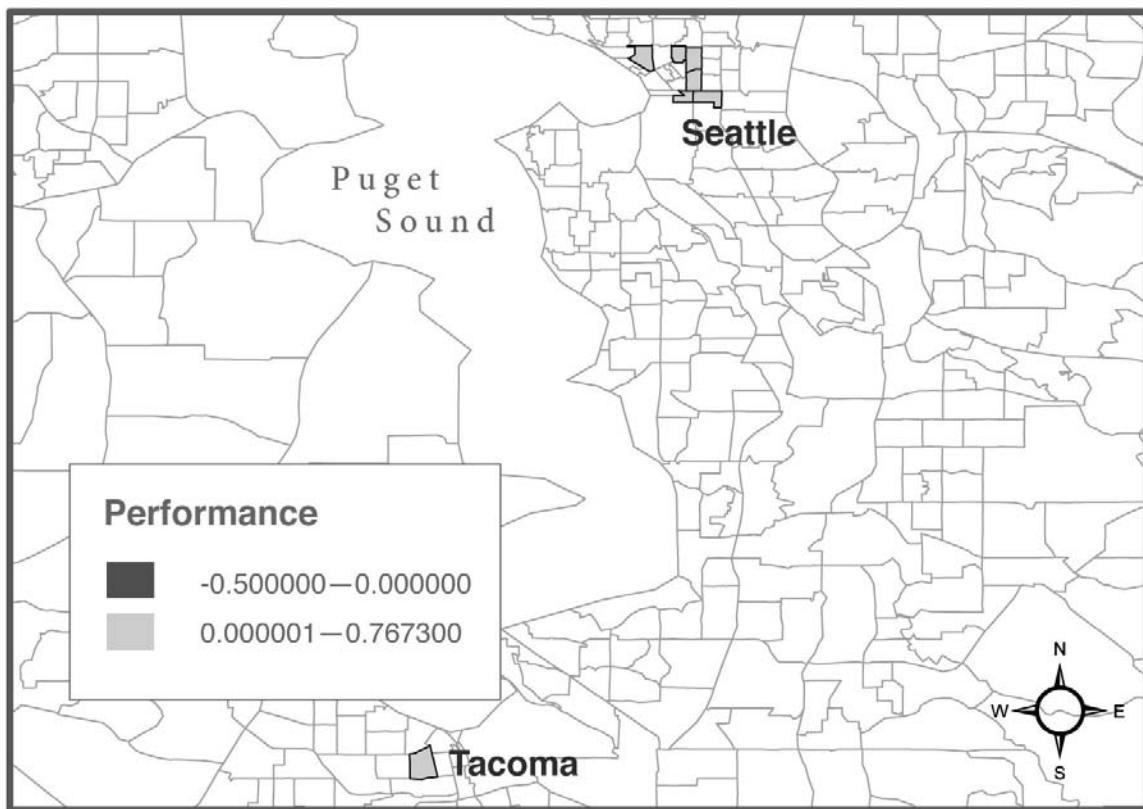

Figure 5. Seattle MSA Target Compared to Control Mean

Figure 6 shows the performance of San Diego MSA census tracts in the target group in relation to the control mean. In this figure, only four QCTs are identified and three of them outperformed the control group. The QCT that declined in performance is located in Escondido, 30 miles to the north. Outperforming QCTs are located in downtown San Diego, a denser area compared to Escondido. Like the Seattle MSA, the San Diego MSA sample size is too small to make generalizations about the performance of QCTs in relationship to their geographic location.

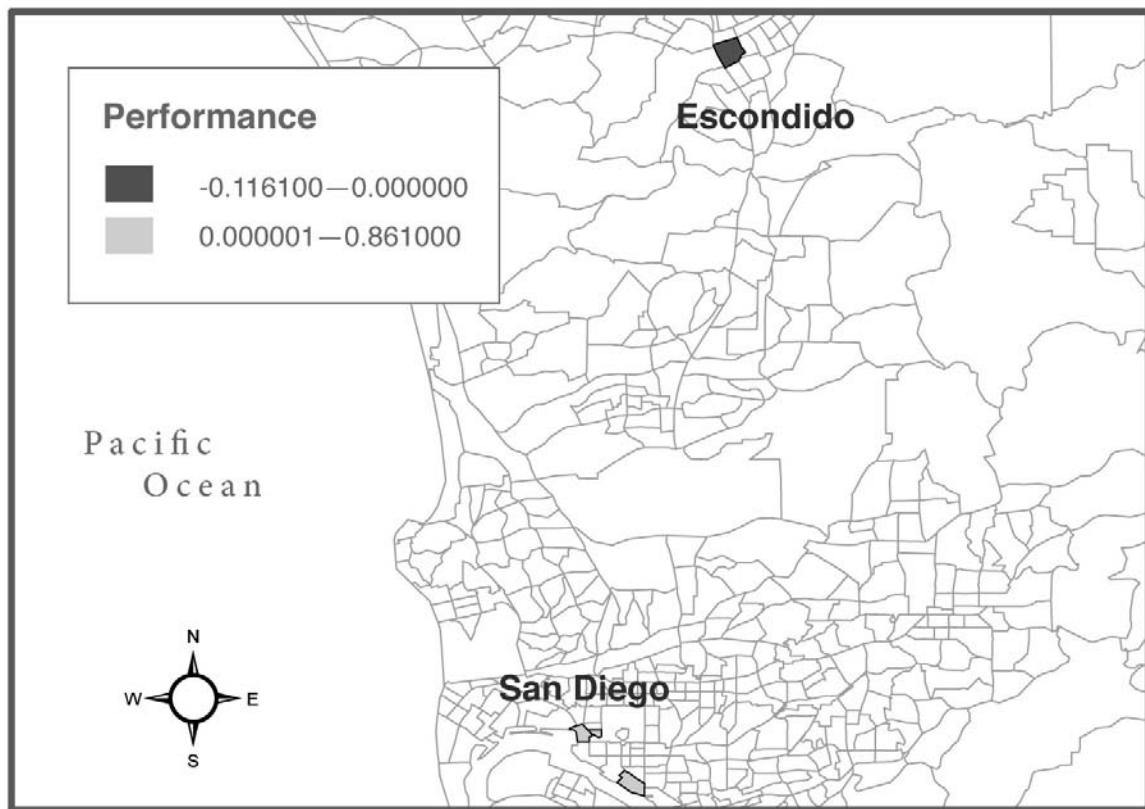

Figure 6. San Diego MSA Target Compared to Control Mean

Figure 7 shows the performance of Dallas MSA census tracts in the target group in relation to the control mean. In this figure, a majority of QCTs underperformed the control group. This is contrary to the performance of many of the other MSAs in this study. Most of these tracts are located within the Lyndon B. Johnson beltway and along the I-30 corridor between Dallas and Fort Worth. Improving tracts are distributed evenly between the two cities.

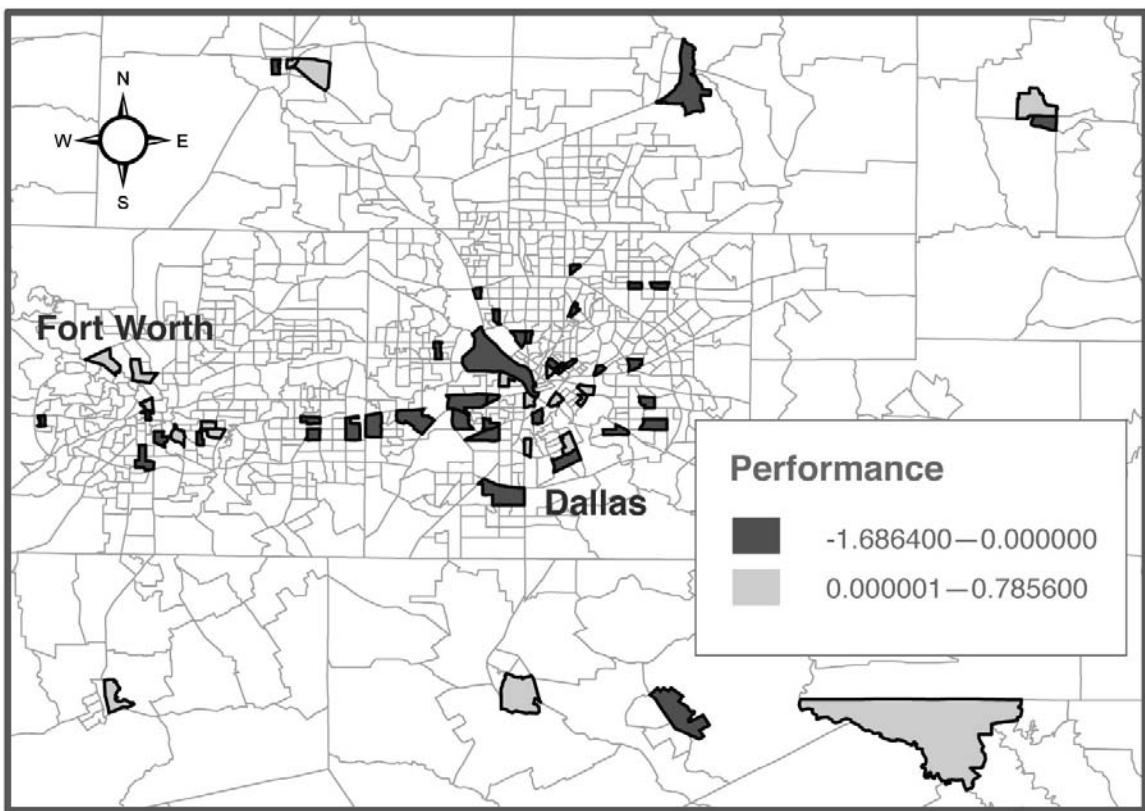

Figure 7. Dallas MSA Target Compared to Control Mean

Figure 8 shows the performance of Houston MSA census tracts in the target group in relation to the control mean. In this figure, few QCTs are located within the district bounded by the I-610 beltway and none are located outside the Sam Houston Tollway. Almost half as many more tracts underperformed the control mean as outperformed in the MSA, but there exists a mix of out- and under-performing tracts in districts outside of the downtown core.

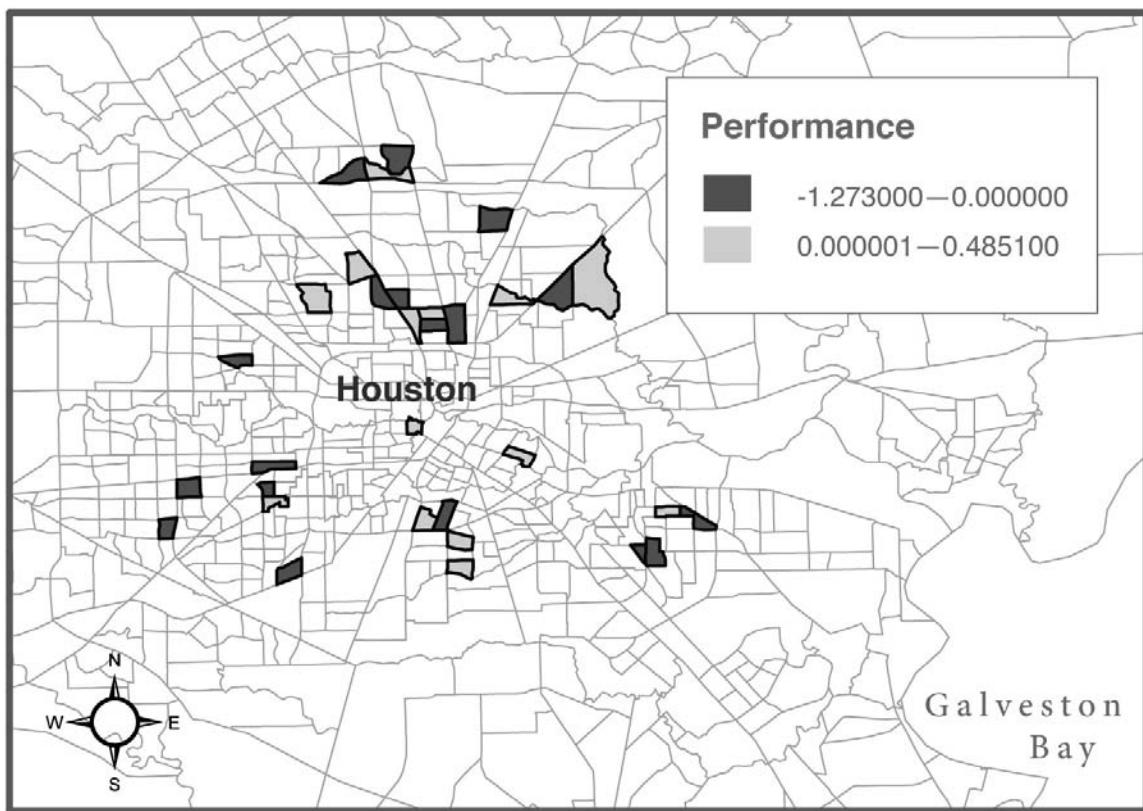

Figure 8. Houston MSA Target Compared to Control Mean

Figure 9 shows the performance of Phoenix MSA census tracts in the target group in relation to the control mean. In this figure, outperforming QCTs are located away from affluent nearby cities like Scottsdale and Glendale and outside of the Phoenix downtown core. The density of outperforming tracts ranges widely. Compared to the other two MSAs in the Southwest region – the Dallas and Houston MSAs – more QCTs in Phoenix MSA outperformed the control.

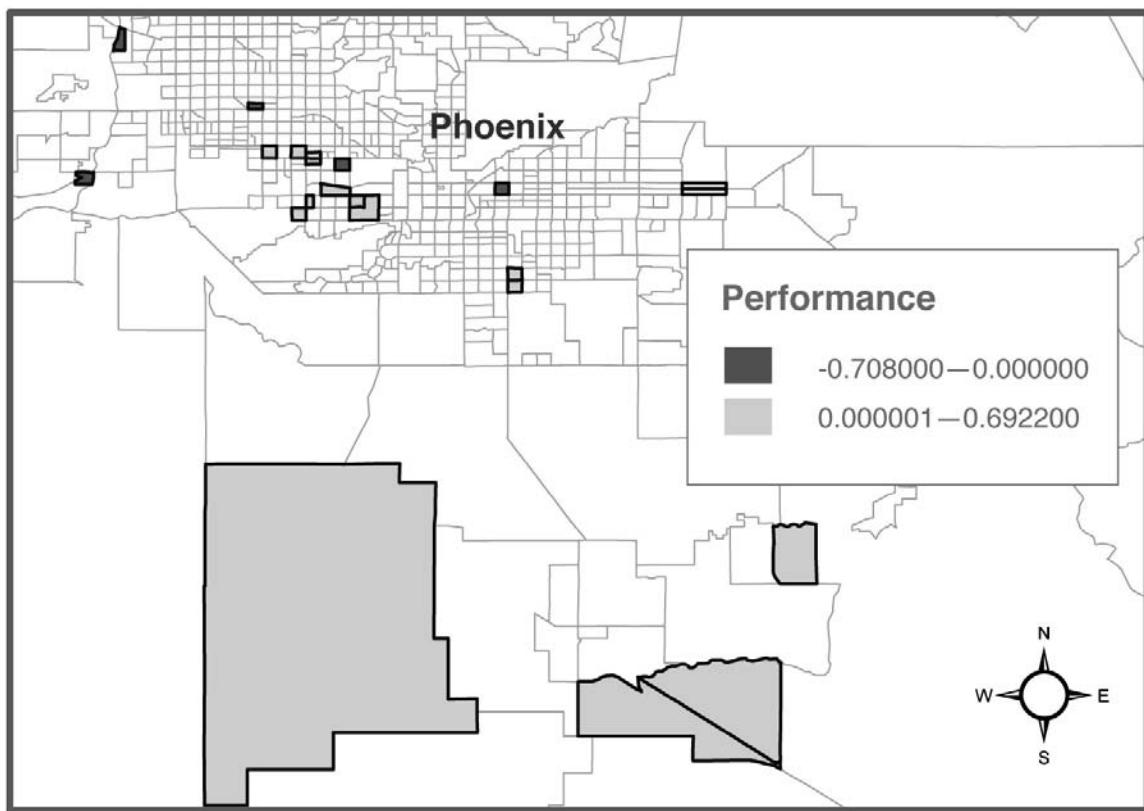

Figure 9. Phoenix MSA Target Compared to Control Mean

Figure 10 shows the performance of Chicago MSA census tracts in the target group in relation to the control mean. In this figure, aggregations of QCTs are located in the Chicago hinterlands of Humboldt Park, North Lawndale, and Lower West Side (all west of the I-94 corridor that separates downtown Chicago from the rest of the metropolis); Fuller Park and Washington Park neighborhoods in the South Side district; and in and around Evergreen Park in the Far Southwest Side district. A cluster of underperforming QCTs is located in the Chatham neighborhood of the Far Southeast Side district.

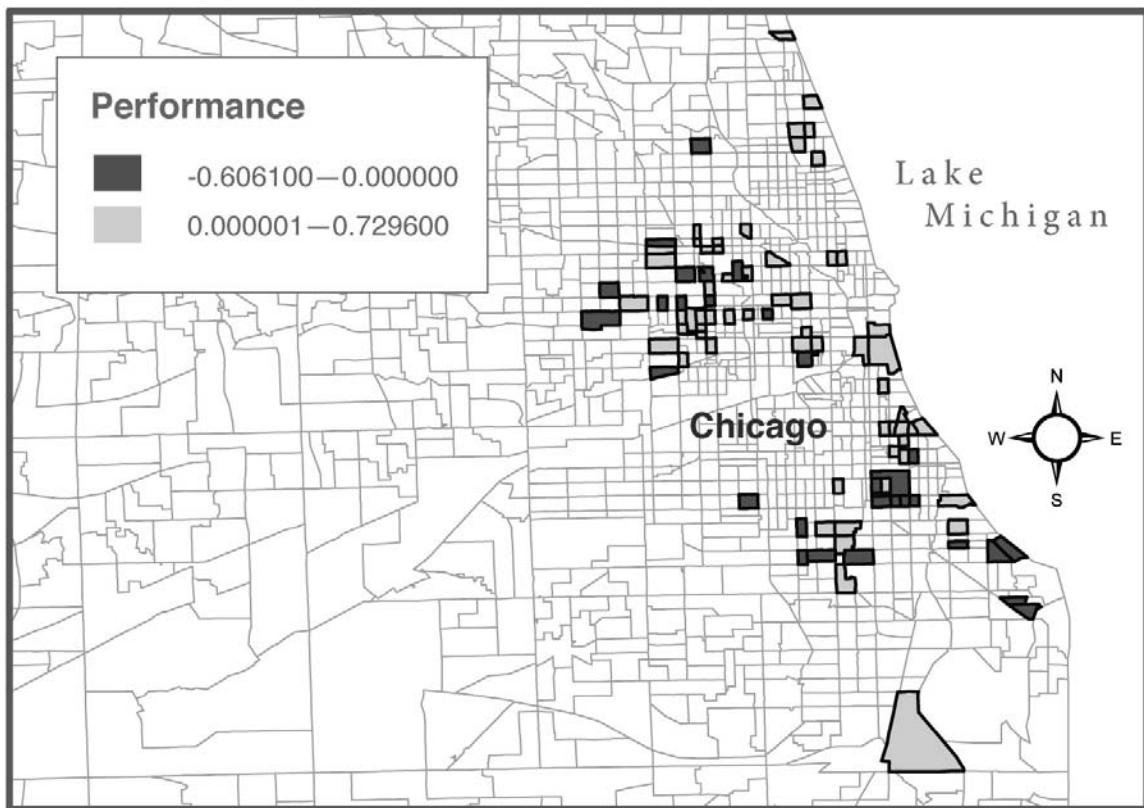

Figure 10. Chicago MSA Target Compared to Control Mean

Figure 11 shows the performance of Detroit MSA census tracts in the target group in relation to the control mean. In this figure, outperforming and underperforming QCTs are located throughout the city within ten miles of the central business district. A band of underperforming QCTs is located along 8 Mile Road. Most outperforming tracts are located in the neighborhoods of Springwells and Islandview. Compared to the other MSAs in the Midwestern Region – the Chicago, Minneapolis and St. Louis MSAs – fewer QCTs in the Detroit MSA outperformed the control.

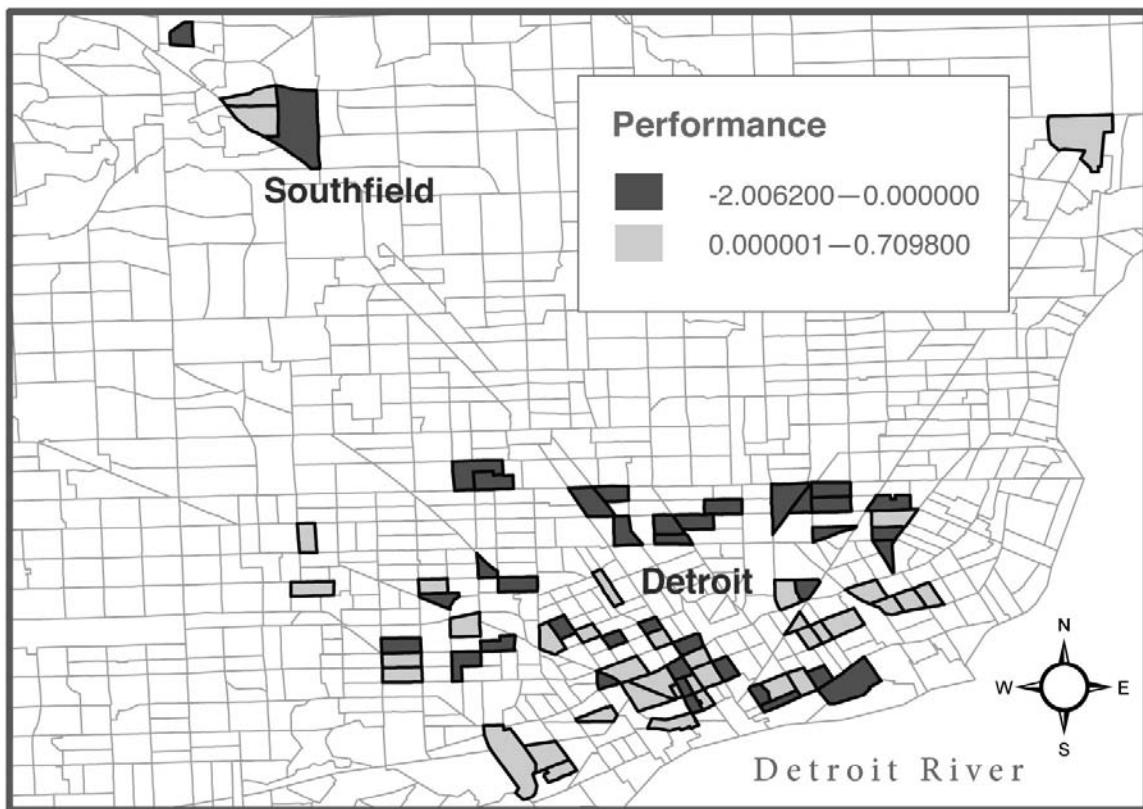

Figure 11. Detroit MSA Target Compared to Control Mean

Figure 12 shows the performance of Minneapolis MSA census tracts in the target group in relation to the control mean. In this figure, there were seven target census tracts that outperformed the control group's mean. Only a small number of total census tracts are QCTs and these are distributed across Minneapolis on the north side of the Mississippi River, away from the downtown core. Like the San Diego and Seattle MSAs, the small sample size in the Minneapolis MSA makes it difficult to determine if there is a relationship between a QCT's performance and geographic location.

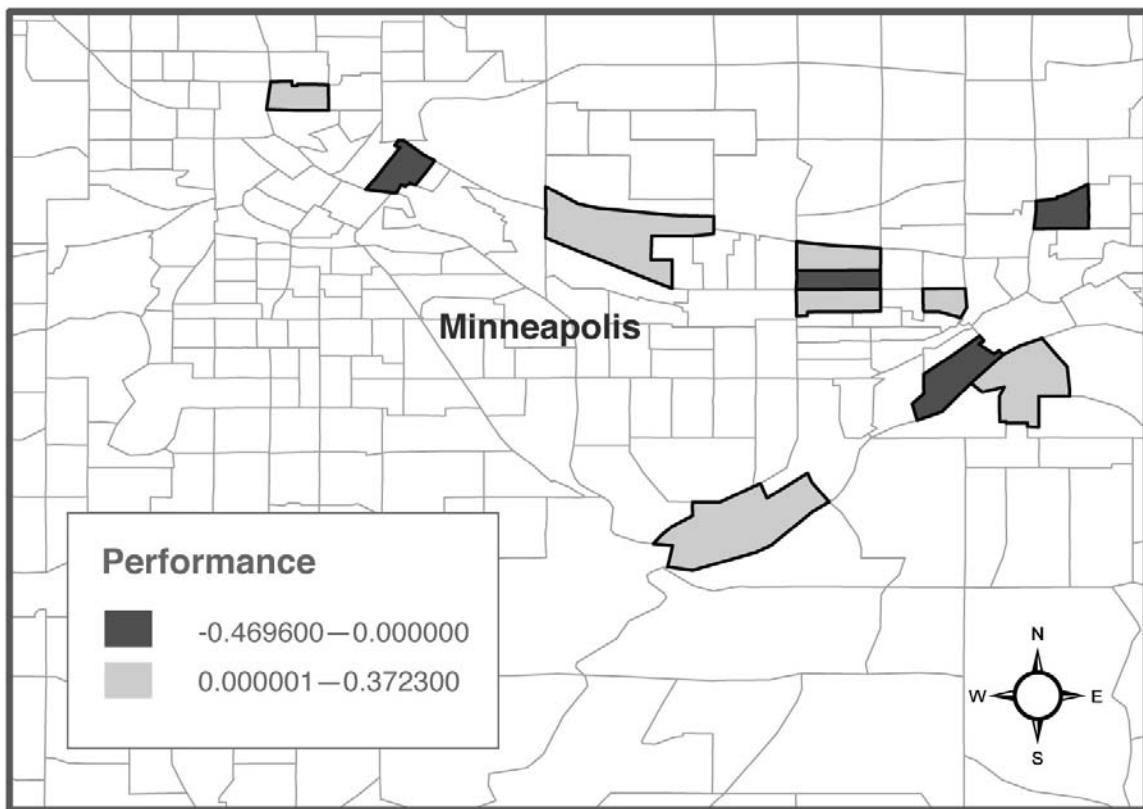

Figure 12. Minneapolis MSA Target Compared to Control Mean

Figure 13 shows the performance of St. Louis MSA census tracts in the target group in relation to the control mean. In this figure, the large aggregation of QCTs outperforming the control group is located entirely within the downtown district of the city north of the I-64 corridor, where a number of African-American neighborhoods are located. St. Louis is one of the most dramatic examples of the relationship between a QCT's performance and its geographic location.

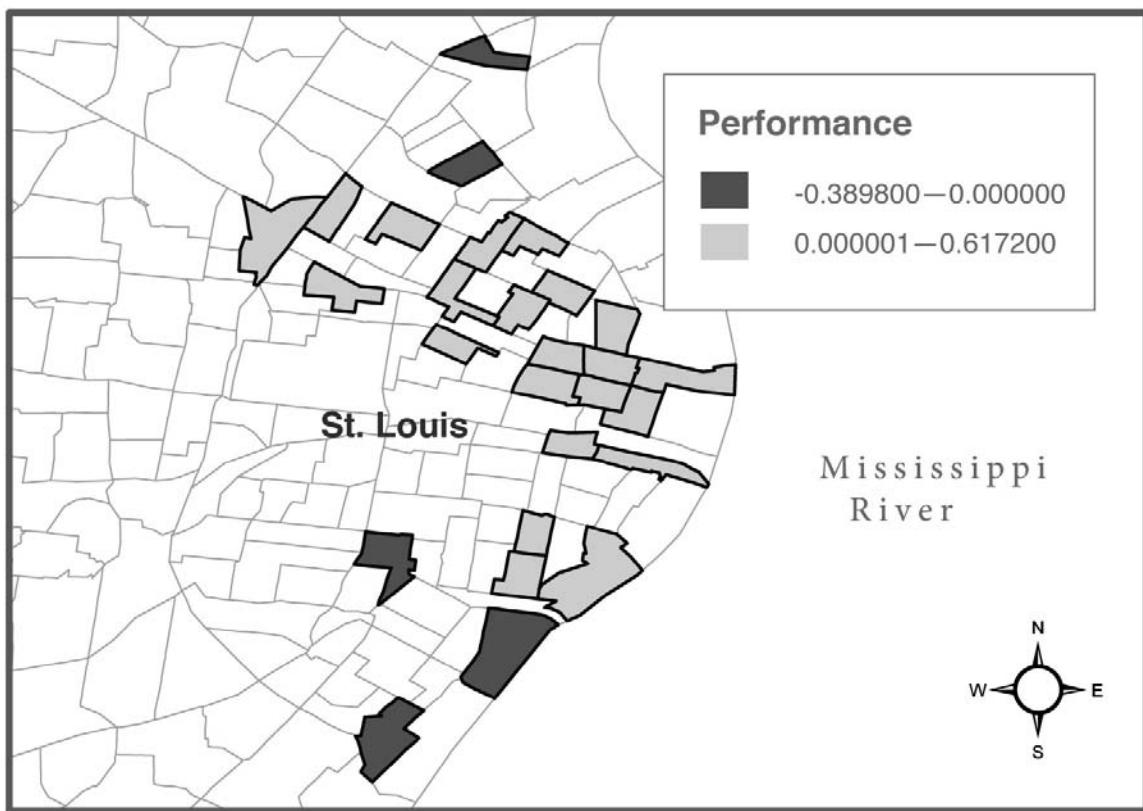

Figure 13. St. Louis MSA Target Compared to Control Mean

Figure 14 shows the performance of New York MSA census tracts in the target group in relation to the control mean. In this figure, a majority of QCTs have outperformed the control group and aggregations are localized in three districts: Harlem, Bronx, and Brooklyn. Specifically, these areas include the Harlem neighborhoods of Hamilton Heights, Central Harlem, and East Harlem; the Bronx neighborhoods of Mott Haven, Longwood, Claremont Village, and Belmont; and the Brooklyn neighborhoods of Bedford-Stuyvesant, Bushwick, Brownsville, and East New York. At the same time, a smaller number of QCTs that underperformed the control group are distributed across the same districts. More so than in other MSAs, the number of immediately adjacent outperforming tracts are notably high in all three QCT districts

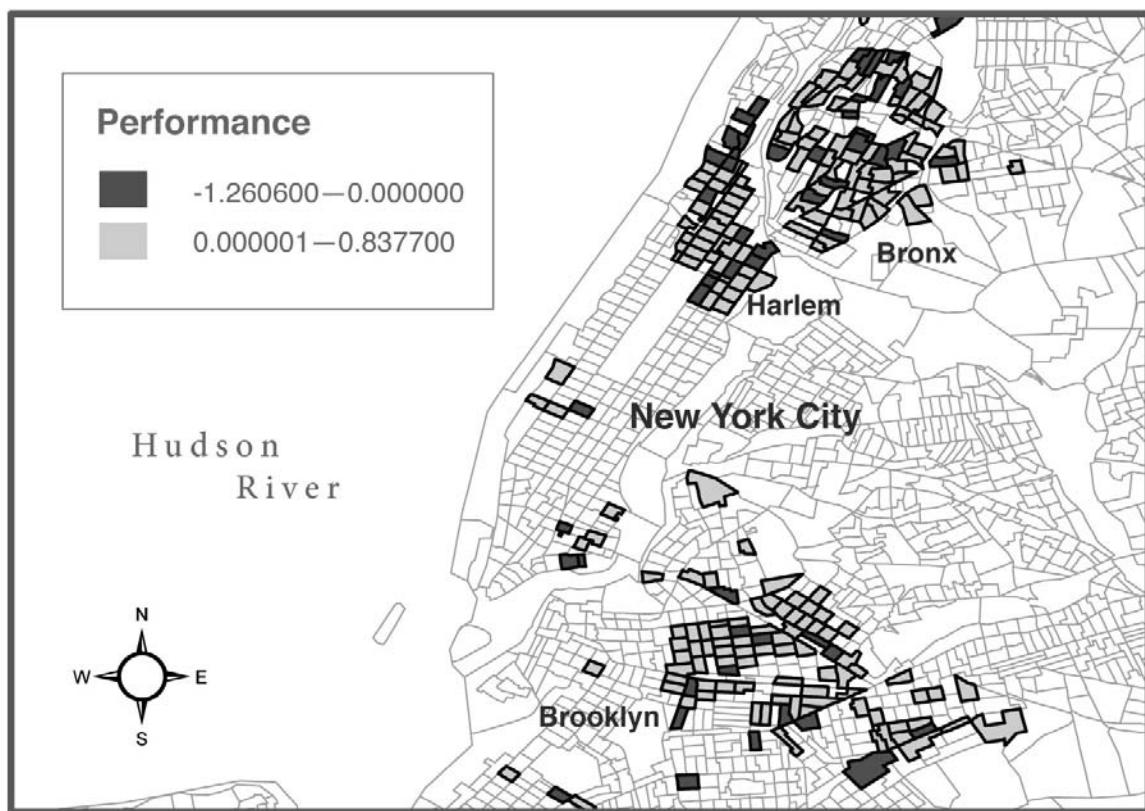

Figure 14. New York MSA Target Compared to Control Mean

Figure 15 shows the performance of Philadelphia MSA census tracts in the target group in relation to the control mean. In this figure, the majority of the target QCTs outperformed the control group and is located primarily within the downtown district between the Schuylkill and Delaware rivers. However, a relatively even distribution of underperforming tracts is found across the city as well.

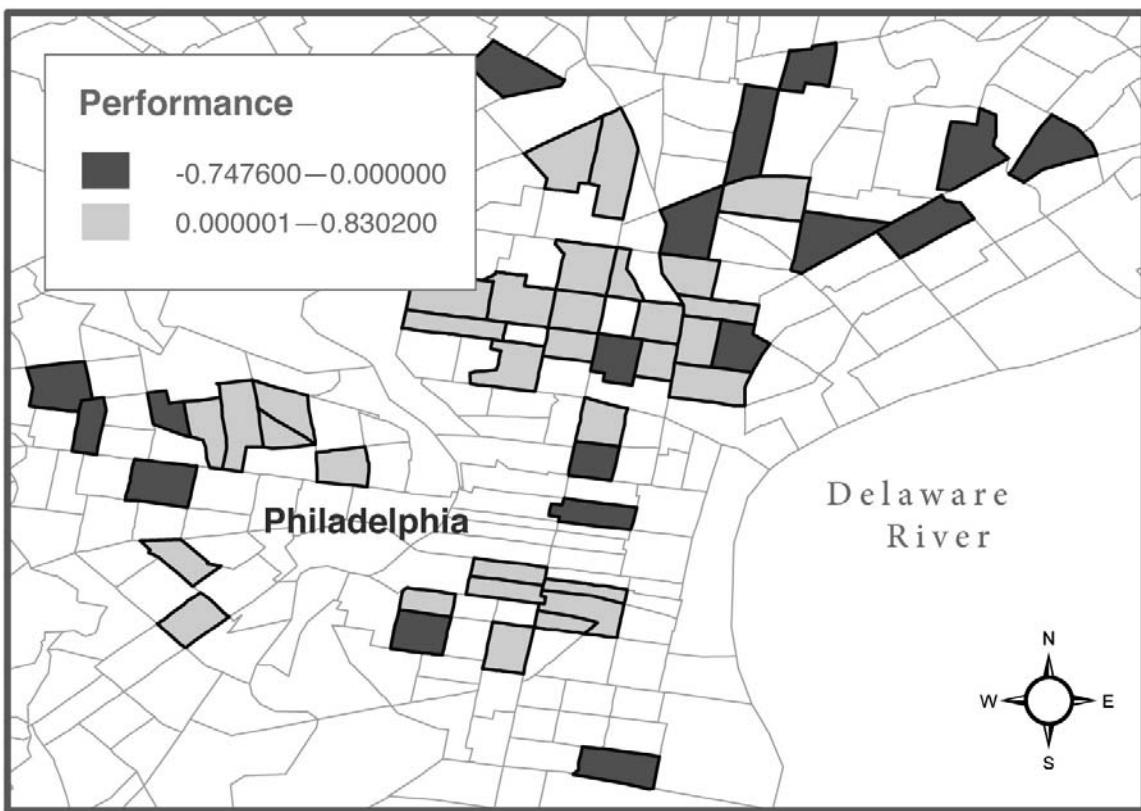

Figure 15. Philadelphia MSA Target Compared to Control Mean

Figure 16 shows the performance of Washington, DC MSA census tracts in the target group in relation to the control mean. In this figure, two distinct areas of the District of Columbia contain QCTs. South of the Anacostia River, an aggregation of underperforming QCTs is located in the Washington Highlands, Randle Highlands, and Upper Central Northeast neighborhoods. A concentration of improving tracts is located in Washington Heights as well. North of the Anacostia, a concentration of improving tracts is located in the Columbia Heights and Cardozo/Shaw neighborhoods.

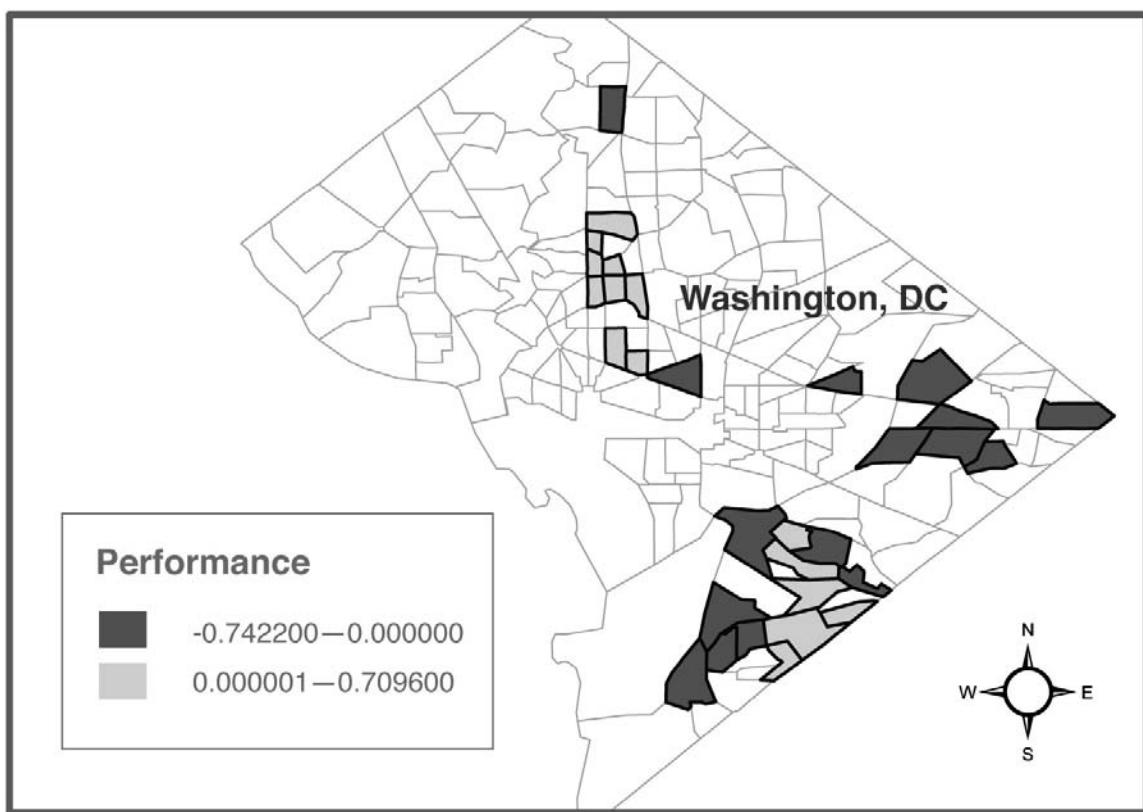

Figure 16. Washington, DC MSA Target Compared to Control Mean

Figure 17 shows the performance of Boston MSA census tracts in the target group in relation to the control mean. In this figure, fewer QCTs outperformed the control group than underperformed, with the majority of underperforming tracts located south of the city's financial district and historic core. Outperforming QCTs are largely located in the Boston's South End district, with two geographically large tracts in the city of Revere five miles north of Boston.

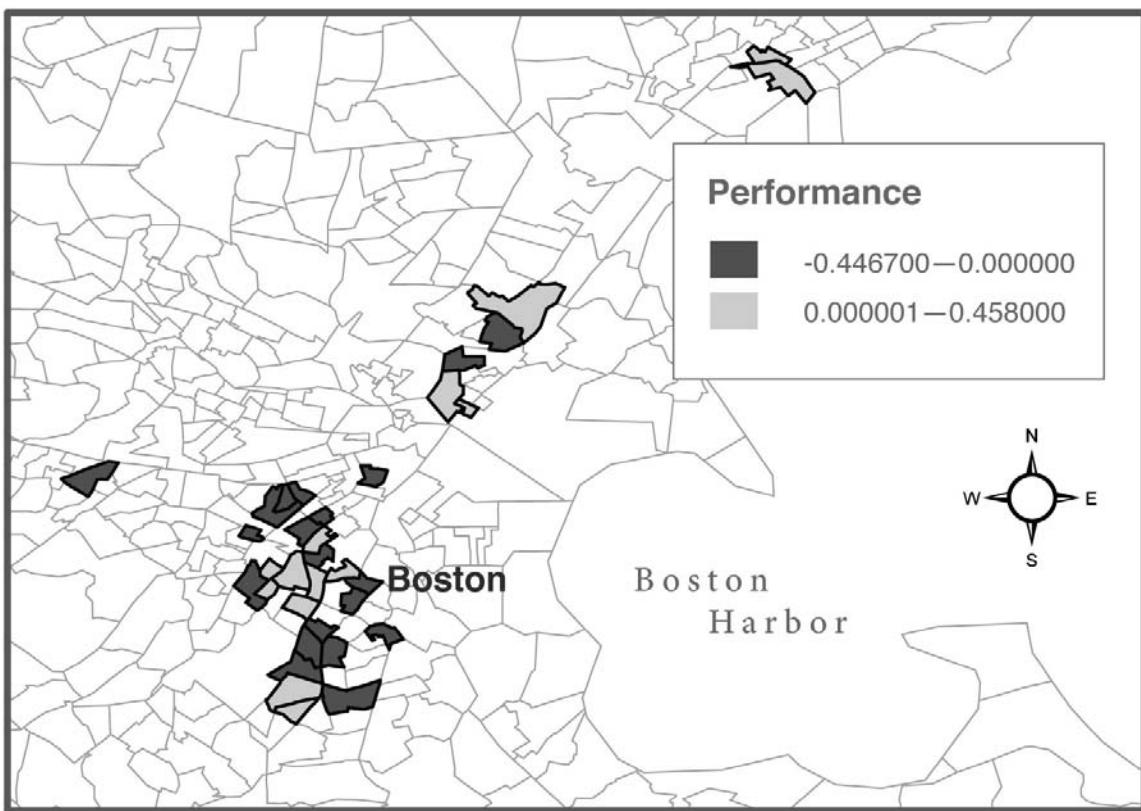

Figure 17. Boston MSA Target Compared to Control Mean

Figure 18 shows the performance of Baltimore MSA census tracts in the target group in relation to the control mean. In this figure, 16 target QCTs outperformed the control group, while only eight declined in performance. Outperforming and underperforming QCTs are largely centralized in and to the north, east, and west of the downtown indicating there may be a relationship between a QCT's performance and its geographic location in the Baltimore MSA. Again, the QCTs that are located in denser areas appear to be outperforming the control mean more frequently than those situated in less dense areas.

Figure 18. Baltimore MSA Target Compared to Control Mean

Figure 19 shows the performance of Miami MSA census tracts in the target group in relation to the control mean. In this figure, twenty-three target QCTs outperformed the control group, while only six declined in performance. Outperforming QCTs are largely located in downtown Miami, Overtown, and Allapattah; all densely urban census tracts within Miami's incorporated boundary. Three of the outperforming census tracts are located in Miami Beach. All target QCTs that were outperformed by the control mean are located in commuter cities outside of the largest incorporated cities, where population density is lower.

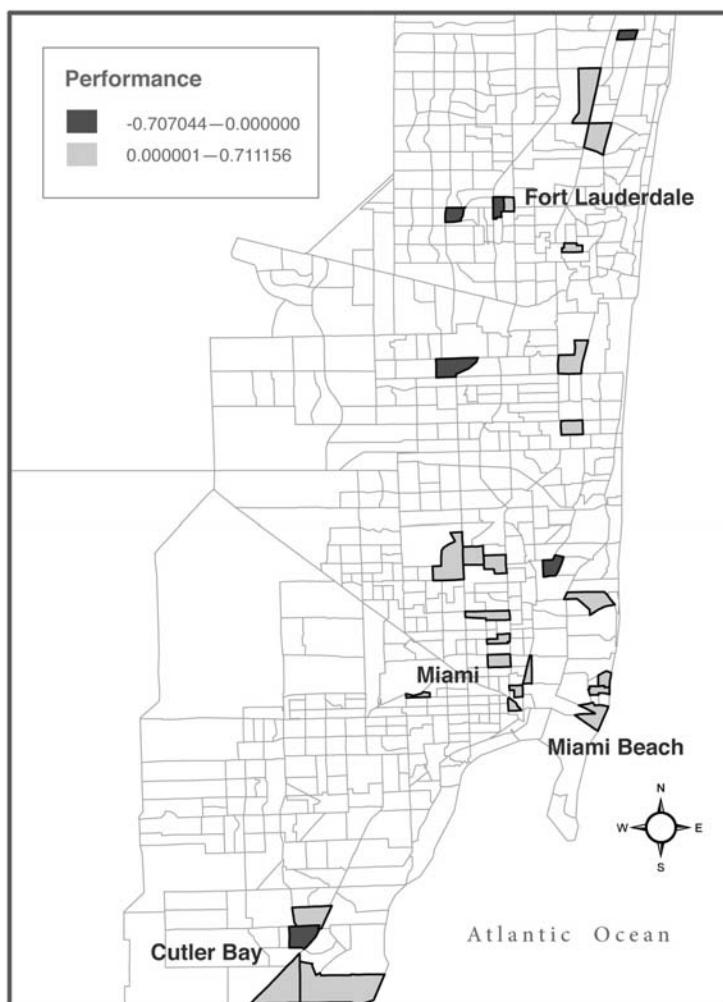

Figure 19. Miami MSA Target Compared to Control Mean

Figure 20 shows the performance of Atlanta MSA census tracts in the target group in relation to the control group mean. In this figure, 17 QCTs outperformed the control group mean, while 19 QCTs were outperformed by the control mean. Outperforming target QCTs are largely clustered in two districts: Neighborhood Planning Units G and D in northeast Atlanta (containing neighborhoods such as Berkeley Park, Blandtown, and Riverside); and downtown Neighborhood Planning Units T, V, L, and M (containing neighborhoods such as English Avenue, Vine City, and Grant Park).

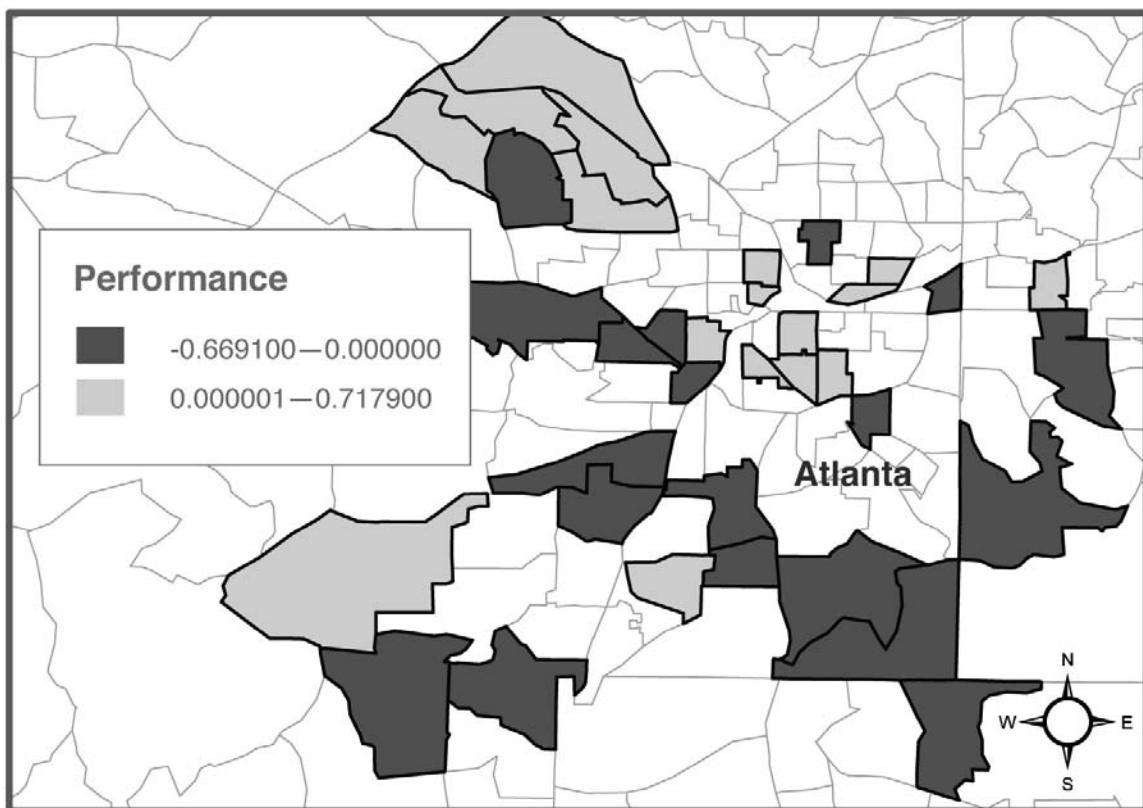

Figure 20. Atlanta MSA Target Compared to Control Mean

Figure 21 shows the performance of Tampa MSA census tracts in the target group in relation to the control group mean. In this figure, 11 target QCTs outperformed the control group mean, while five were outperformed by the control mean. Outperforming target QCTs were primarily located in densely residential downtown Tampa districts such as Ybor City, Northview Hills, and Southeast Seminole Heights. Of those target QCTs that were outperformed by the control mean, the largest one by size was Del Rio, one of the least dense neighborhoods in the MSA.

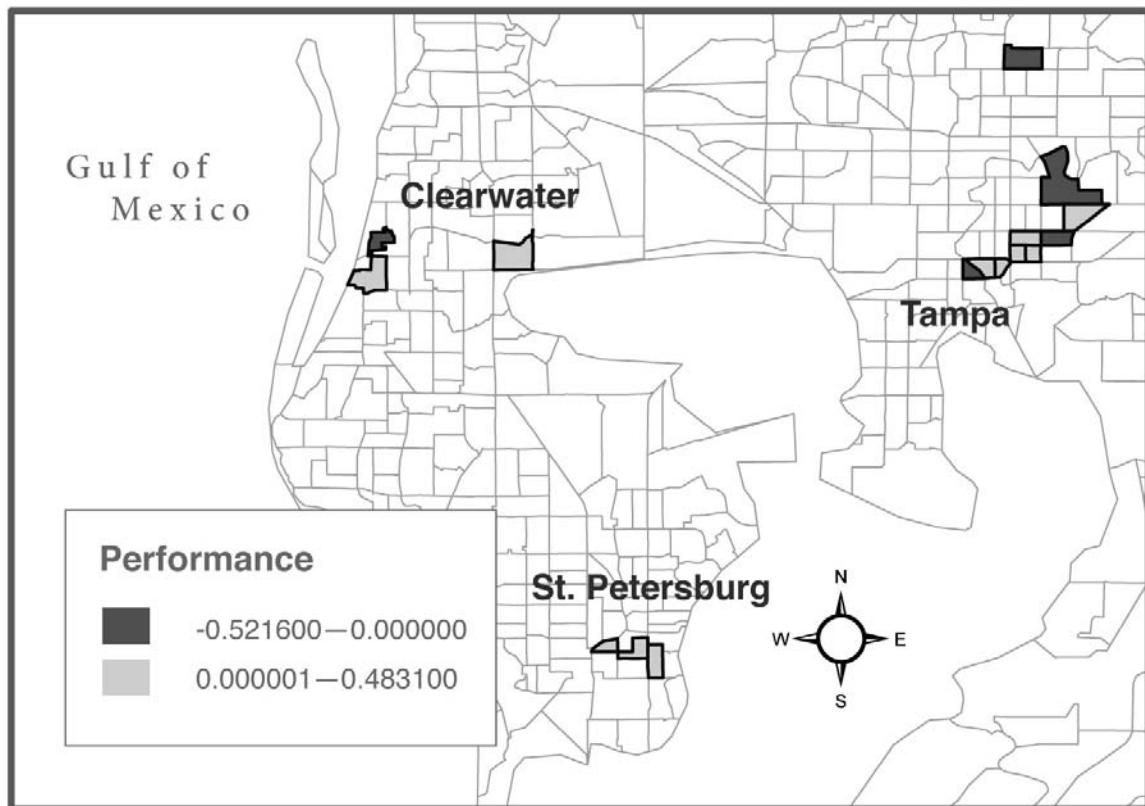

Figure 21. Tampa MSA Target Compared to Control Mean

CHAPTER 5: DISCUSSION AND RECOMMENDATIONS

The last chapter of this paper discusses the implications of the research findings and provides several explanations as to why the target group may be outperforming the control group. The performance of the individual variables is also discussed. The limitations of the study are identified and several policy suggestions based on the findings of this study are presented. Last, trajectories for future related research are identified.

5.1 Discussion of the Implications of Findings

The findings of the research indicate a greater number of QCTs with LIHTC development socioeconomically outperform QCTs without LIHTC projects. This suggests that LIHTC development is not perpetuating poverty or existing conditions in QCTs. Additionally, it appears the geographic distribution of outperforming QCTs often aligns more closely in this study with higher density. This finding is consistent with the study conducted by Deng (2009) that reveals a pattern of improvement for LIHTC housing located in high-poverty inner-city neighborhoods.

Many reasons may help explain why LIHTC QCTs have outperformed their control counterparts. One such explanation may be related to the replacement of substandard public housing projects in dense, low-income neighborhoods with LIHTC development. Under the LIHTC program, at least 20 percent of the units must be occupied by renters whose income is 50 percent or less of the area median gross income

or at least 40 percent of the units must be occupied by renters whose income is 60 percent or less of the area median income (Keightley 2009). Tenants with incomes less than 30 percent of the area median gross income usually occupy public housing. Compared to public housing residents, LIHTC residents usually have higher incomes, are more likely to have earned income, and are less likely to be on public assistance (Oakley 2008). Improving socioeconomic conditions of certain census tracts may then simply reflect the displacement of public housing residents by higher income LIHTC residents and not by the actual socioeconomic improvement of existing low-income residents.

Socioeconomic improvement in QCTs with LIHTC housing may also be attributable to the fact that tax credit projects are often part of a larger community redevelopment program featuring other revitalization efforts that improve socioeconomic conditions in low-income neighborhoods. Many QCTs in urban areas have not seen new investment in decades, so the development of LIHTC housing could be spurring reinvestment activity. The study conducted by Cummings and DiPasquale (1999) indicates that LIHTC development comprises the only new residential construction activity in many of the neighborhoods where it is built.

The management structure for LIHTC housing developments is also different from traditional low-income housing projects, with private management companies often maintaining LIHTC properties to higher standards. This is consistent with the fact that LIHTC housing tends to be designed to higher design and appearance standards that increase the perception of local neighborhood character. In addition, some LIHTC developments have been built for targeted populations (e.g., live-work lofts for artists and age-restricted developments for senior citizens), which create more stable and

community-oriented neighborhoods. All these factors may help explain why more QCTs with LIHTC development outperformed control QCTs.

There were only two MSAs, the Dallas and Houston MSAs, where the control group outperformed the target group and the results were statistically significant. It is also interesting to note that Dawkins (2011) found Houston to be a clear outlier as well. The results of that study indicate that LIHTC projects in Houston exhibited the lowest level of clustering compared to nine other metropolitan areas examined; clusters were not significant beyond three to four miles from the city core and there were fewer clusters in QCTs, DDAs, high poverty areas, and majority-Black neighborhoods (Dawkins, 2011).

One factor suggested for why Houston and Dallas are outliers was the Texas Qualified Allocation Plan. The Texas QAP requires LIHTC development to be located at least one mile from one another and avoid census tracts that already have a large number of affordable housing units. Dawkins (2011) also cites another reason that may be related to the lower development densities. In Dallas and Houston, it is likely that there is more developable land suitable for LIHTC development compared to other cities. Dawkins' results for the Dallas and Houston MSAs seem to be consistent with the literature. If LIHTC QCTs are more likely to outperform their control when concentrated in high-poverty inner-city neighborhoods, it is expected that LIHTC QCTs will not perform as well in Dallas and Houston since projects are less clustered in high-poverty minority neighborhoods.

Although the QCTs with LIHTC projects overwhelmingly outperformed the control groups, this does not imply that the socioeconomic variables improved overall. In fact, education was the only variable that consistently improved over the last two decades

in this study. This is consistent with the educational attainment trend identified by the U.S. Census Bureau wherein the total population 25 years of age and older graduating high school has progressively been increasing since the 1950s (U.S. Census Bureau, 2004). The performance of the socioeconomic index and remaining variables varied across locations. Unemployment had the greatest amount of variation and seemed to be the least related to the performance of the other variables.

5.2 Limitations of the Study

There are several limitations of this study. There were census tracts in both the control and target groups that had to be eliminated because data was not available or the census tract boundaries changed over the last, precluding the opportunity to do a before-and-after comparison. Consequently, a number of QCTs could not be included in this study. The elimination of the census tracts that had LIHTC projects built before 1990 may be of the most concern since many of these tracts contained the largest concentrations of LIHTC units.

As discussed in the methodology section, the margin of error was not taken into consideration for this study because of the complexity of the calculation for the 1990 Census data. In future studies, where the dataset may not be as large, the margin of error can be calculated for the 1990 data using the standard errors and margin of errors formula provided by the U.S. Census Bureau to obtain an estimate about the true interval for each variable in each tract.

All the variables in the socioeconomic index were weighted equally. No prior research indicated how the four variables in this study should be weighted. Assigning a weight to each of these variables would have been arbitrary; therefore, it was decided to

weight each variable equally. Several methods, such as Principal Component Analysis, were utilized to address the weighting issue but the results of these analyses were inconclusive and not feasible to use.

The LIHTC database does not indicate if a project actually received the 30 percent bonus for being located in a QCT. This study assumes that all LIHTC projects built in QCTs received the basis boost, but such an assumption may overstate the number of projects receiving incentives for the QCT provision.

In the discussion, there were several reasons cited for why QCTs with LIHTC projects generally outperformed QCTs without LIHTC development socioeconomically. Unfortunately, some of these trends cannot be tested because of a lack of available data. For instance, HUD does not keep data on the number of public housing projects that have been replaced by tax credit projects and whether public housing tenants relocated. Therefore, it is impossible to determine if the changes of the census tracts may simply reflect the displacement of public housing residents by higher income LIHTC residents rather than the actual socioeconomic improvement of existing low-income residents.

5.3 Policy Suggestions

There is concern that the LIHTC program lacks oversight in its administration and is inadequately monitored. With the IRS as its primary administrator, there is no distinct federal, state, or local agency responsible for monitoring the LIHTC program and no federal requirements for poverty deconcentration or related goals. The nation's largest affordable housing production program is often criticized for not receiving enough policy direction at the federal level and for leaving state housing agencies with excessive flexibility.

The LIHTC literature demonstrates that the kind and depth of direction provided in state Qualified Allocation Plans might, in fact, impact LIHTC program performance and outcomes. However, the lack of reporting requirements makes it difficult to fully understand and study these impacts or the extent to which the program is creating economically diverse housing opportunities. Researchers have suggested that data collection be required for the LIHTC program as similarly required by H.R. 3211 for other HUD programs. This data includes, but is not limited to: racial, ethnicity, and economic data on project residents; number of HCV holders residing in each property; and a description of the developers' proposed affirmative marketing plan. Such data collection and monitoring would allow for LIHTC program performance outcomes to be measured and thus help direct future policy considerations.

The federal government may consider requiring state housing agencies to place LIHTC development in areas that further fair housing goals and avoid segregation. If greater emphasis is placed on using LIHTC as a means to expand opportunities for low-income residents instead of continuing its current primary use as a neighborhood revitalization tool, then state Qualified Allocation Plans will need to include set-asides for development in more affluent neighborhoods. Allowing the LIHTC program to be used for scattered site development may also function as a tool to expand opportunities and desegregate housing patterns. State housing agencies should also be required to submit the criteria outlined in Qualified Allocation Plans aimed at poverty deconcentration and the elimination of housing segregation on an annual basis to the federal government.

The Housing and Economic Recovery Act of 2008 made the QCT bonus available to projects outside of DDA and QCT areas. The provision added a third type of high-cost area eligible for the bonus boost. State allocating agencies may now extend the 30 percent credit to any project that demonstrates the credit is needed to be financially feasible (Joint Committee on Taxation, 2008). However, again the federal government has provided minimal direction to state allocating agencies on how they should set standards for determining which projects should be allocated additional credits. Similarly, the bonus boost is determined based on financial feasibility and is not required to take into consideration the existing concentration of LIHTC units or current socioeconomic conditions.

Even though the QCT provision is not negatively impacting socioeconomic conditions in all local housing markets, the QCT bonus can be revised. Policymakers should aim to balance the two goals of the LIHTC program; revitalizing distressed neighborhoods and expanding opportunities for low-income residents. A bonus could be given for development located in areas that expand opportunities for low-income residents. Examples include locating LIHTC properties in employment- and opportunity-rich areas with adequate educational facilities. As with the Texas Qualified Allocation Plan, points can be awarded for projects located in a census tract with no other LIHTC units. Points can also be awarded for developing family LIHTC units specifically in neighborhoods with higher-than-average household AMIs. Regardless of how the points are allocated, there needs to be oversight and reporting requirements to ensure state allocating agencies and LIHTC projects are in compliance with Fair Housing Laws and are balancing the goals established for the LIHTC program.

5.4 Future Research

Further examination of the abovementioned factors, in addition to other variables that may explain socioeconomic conditions, is worthwhile for future study. To further examine how the concentration of LIHTC units impacts socioeconomic conditions in a tract, the relationship between the concentration of LIHTC projects and socioeconomic variables (poverty, income, unemployment, and education) in QCTs can be examined. Bivariate correlation may be used to measure the degree of correlation between the concentration of LIHTC units and the socioeconomic index and other neighborhood indicators. The percentage share of LIHTC units, particularly that of low-income housing units, among all housing units may be used to measure the concentration of LIHTC units in neighborhoods. In addition, since the geographic distribution of outperforming QCTs appears to be aligned closely with higher density, the performance of QCTs with LIHTC development in relationship to population density and housing density can be examined. Several of the MSAs will be selected for a case study analysis performed at the local level. This detailed analysis will include examination of development patterns from orthophotos, newspaper records, municipally-adopted redevelopment plans, and other repositories of historical information.

Preliminary study of the Atlanta and St. Louis MSAs found that concentration of LIHTC units and population and housing density do not have significant associations with the change of neighborhood indicators or the socioeconomic index. However, results from this research indicate that QCTs with LIHTC units socioeconomically improved when compared to similar QCTs without LIHTC units. This may imply the spillover effect of LIHTC units on neighborhoods, although the direct effect might not be

identifiable. The findings of further research are likely to reveal the extent that LIHTC units have on distressed neighborhoods and thus more firmly demonstrate whether LIHTC projects in QCTs exacerbate the concentration of poverty. Such findings would subsequently be valuable in formulating guidelines for future LIHTC allocation in high-poverty neighborhoods.

APPENDIX A: INDEPENDENT SAMPLE T-TESTS
